Rate of Divergence of the Nonparametric Likelihood Ratio Test for Gaussian Mixtures

Wenhua Jiang * and Cun-Hui Zhang †

Abstract

We study a nonparametric likelihood ratio test (NPLRT) for Gaussian mixtures. It is based on the nonparametric maximum likelihood estimator in the context of demixing. The test concerns if a random sample is from the standard normal distribution. We consider mixing distributions of unbounded support for alternative hypothesis. We prove that the divergence rate of the NPLRT under the null is bounded by \( \log n \), provided that the support range of the mixing distribution increases no faster than \((\log n / \log 9)^{1/2}\). We prove that the rate of \( \sqrt{\log n} \) is a lower bound for the divergence rate if the support range increases no slower than the order of \( \sqrt{\log n} \). Implications of the upper bound for the rate of divergence are discussed.

Keywords: Likelihood ratio test, Gaussian mixtures, rate of divergence, two-component mixtures, Hermite polynomials.

1 Introduction

Define the standard normal location-mixture density

$$f_G(x) = \int \varphi(x - u)dG(u),$$

(1.1)

where \(\varphi(x) = \exp(-x^2/2)/\sqrt{2\pi}\) is the standard normal density. Let \(\mathcal{G}\) be the collection of all distributions in the real line \(\mathbb{R}\) and take \(\mathcal{F} = \{f_G: G \in \mathcal{G}\}\) as the family of all standard normal location-mixture densities. Let \(X_1, \ldots, X_n\) be independent and identically distributed observations with probability density function \(f\). We consider testing the null hypothesis that the sample is generated from \(\varphi\) against the general alternative that the sample is from a mixture density \(f_G \in \mathcal{F}\) other than \(\varphi\). For \(f_1, f_2 \in \mathcal{F}\), the log-likelihood ratio is defined as

$$\ell_n(f_1, f_2) = \sum_{i=1}^{n} \log \frac{f_1(X_i)}{f_2(X_i)}.$$

Let \(\mathcal{F}_n \subset \mathcal{F}\) be a sequence of density families. For testing \(H_0: f = \varphi\) against \(H_1: f \in \mathcal{F}_n \setminus \{\varphi\}\), the nonparametric likelihood ratio test (NPLRT) statistic is

$$\sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) = \ell_n(\hat{f}_n, \varphi),$$

(1.2)

where \(\hat{f}_n = \arg\max_{f \in \mathcal{F}_n} \prod_{i=1}^{n} f(X_i)\) is the nonparametric maximum likelihood estimator (NPMLE, Robbins, 1950; Kiefer and Wolfowitz, 1956) of normal mixture density. We are interested in the case where

$$\mathcal{F}_n = \{f_G: G([-M_n, M_n]) = 1\}$$

(1.3)

with \(M_n > 0\), especially \(M_n \to \infty\).

The MLE in (1.2) is nonparametric in the sense that \(\mathcal{F}_n\) is a family of “infinite Gaussian mixture”, instead of the well known finite mixtures. It is widely thought that the analysis of the NPMLE is challenging (e.g., DasGupta, 2008, Chapter 33). What are the asymptotic properties of the NPLRT? First of all, \(\hat{f}_n\) is consistent (Ghosal and van der Vaart, 2001; Zhang, 2009). Due to loss of identifiability, the asymptotic distribution of the NPLRT is not the usual \(\chi^2\) distribution. Hartigan (1985) discovered that under the null, the NPLRT diverges to infinity in probability as \(M_n \to \infty\). Jiang and Zhang (2016) proved that when \(\mathcal{F}_n = \mathcal{F}\), the rate of divergence is bounded by \((\log n)^2\). Gu, Koenker and Volgushev (2013) provided interesting numerical results for the asymptotic behaviors of the test under different settings. Liu and
Shao (2003) considered asymptotics of likelihood ratio tests under loss of identifiability. Azaïs, Gassiat and Mercadier (2009) considered the asymptotic null distribution of the NPLRT with mixing distributions of bounded support. See Section 4 for some asymptotic properties of the parametric LRT (PLRT).

The notation to be used is listed first for easy reference. We will use the abbreviation \( \mathbb{P}f = \mathbb{E}f(X) \) for an integrable function \( f \). Its empirical counterpart is denoted by \( \mathbb{P}_nf = \frac{1}{n} \sum_{i=1}^{n} f(X_i) \). In this paper, the expectation \( \mathbb{P} \) is taken with respect to the standard normal density \( \varphi \). For \( \rho \in \mathcal{L}_p(\mathbb{P}) \), define the \( \mathcal{L}_p(\mathbb{P}) \) norm as \( \|f\|_p = \left\{ \mathbb{P}(f^p) \right\}^{1/p} = \left\{ \int |f(x)|^p \varphi(x) dx \right\}^{1/p} \). The Hellinger distance between two densities \( f \) and \( g \) is defined as \( d^2(f,g) = \frac{1}{2} \int (\sqrt{f} - \sqrt{g})^2 dx \). Given a collection \( \mathcal{F} \) of \( \mathcal{L}_1(\mathbb{P}) \) functions, the \( \mathcal{F} \)-indexed empirical process \( \nu_n \) is given by \( \nu_n f = \sqrt{n} (\mathbb{P}_n - \mathbb{P}) f, f \in \mathcal{F} \). Throughout the paper, \( x \wedge y = \min(x, y) \), \( x_+ = \max(x, 0) \) and \( a_n \asymp b_n \) means \( 0 < a_n/b_n + b_n/a_n = O(1) \).

The following theorem summarizes some results based on Ghosal and van der Vaart (2001), Jiang and Zhang (2009) and Jiang and Zhang (2016).

**Theorem 1.** There exists \( \{f_{G_j}, 1 \leq j \leq N_n\} \subset \mathcal{F}_n \) and \( \varepsilon_n \asymp n^{-1/2} \log n \) such that \( \log N_n \leq n \varepsilon_n^2 \), \( \max_{1 \leq j \leq N_n} d(f_{G_j}, \varphi) \leq \varepsilon_n \) and

\[
\sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) = (1 + \eta_n) \sup_{1 \leq j \leq N_n} \ell_n(f_{G_j}, \varphi) \leq n \varepsilon_n^2
\]

with large probability, where \( |\eta_n| \asymp 1/n \).

Theorem 1 says that the NPLRT is nearly achieved by a finite collection of Gaussian mixtures \( \{f_{G_j}, 1 \leq j \leq N_n\} \) of manageable size. This collection can be regarded as approximate NPMLEs such that \( d(f_{G_j}, \varphi) \leq \varepsilon_n \) for all \( 1 \leq j \leq N_n \). In this paper, as mentioned in (1.3), we allow the support range of mixing distribution goes to infinity. We prove that the order of the NPLRT in (1.2) is bounded by \( \log n \) in probability, provided that the support range of the mixing distribution goes to infinity no faster than \( (\log n/\log 9)^{1/2} \). This gives an upper bound. The discretization in Theorem 1 is an element for the analysis of upper bound. We prove that the rate of \( \sqrt{\log n} \) is a lower bound for the divergence rate if the support range increases no slower than the order of \( \sqrt{\log n} \).

The rest of this paper is organized as follows. The Hermite polynomial expansion of Gaussian mixtures is introduced in Section 2. In Section 3 we study the upper bound for the rate of divergence of the NPLRT. The lower bound is given in Section 4. The implications of the
rate of divergence, some simulations and other mixtures are discussed in Section 5. Proofs are
given in Section 6.

2 The Hermite Polynomial Expansion

As in Azaïs, Gassiat and Mercadier (2009), our analysis is based on the expansion of
Gaussian mixtures by Hermite polynomials. The Hermite polynomials are defined as
\[
H_k(x) = (-1)^k e^{x^2/2} \frac{d^k}{dx^k} e^{-x^2/2}
\]  
(2.1)
with \( H_0(x) = 1, H_1(x) = x, H_2(x) = x^2 - 1 \), etc. It is well known that \( \int H_j(x)H_k(x)\varphi(x)dx = k! I\{j = k\} \). The Gaussian mixtures have the expansion
\[
f_G(x) = \varphi(x) \sum_{k=0}^{\infty} \frac{\mu_k(G)}{k!} H_k(x),
\]  
(2.2)
where \( \mu_k(G) = \int u^k dG(u) \) is the \( k \)-th moment of \( G \). Let
\[
h_G(x) = \frac{f_G(x)/\varphi(x) - 1}{\|f_G/\varphi - 1\|_2}
\]  
(2.3)
be the generalized score function (Liu and Shao, 2003). Note that the likelihood ratio \( f_G/\varphi \) is
square integrable. It follows from the expansion above that for \( f_G \neq \varphi \),
\[
h_G(x) = \sum_{k=1}^{\infty} c_k(G) \frac{H_k(x)}{\sqrt{k!}},
\]  
(2.4)
where \( c_k(G) = \{\mu_k(G)/\sqrt{k!}\} / \{\sum_{j=1}^{\infty} \mu_j^2(G)/j!\}^{1/2} \).

Define two envelope functions
\[
F_{1,n}(x) = \left\{ \sum_{k=1}^{m} \frac{H_k^2(x)}{k!} \right\}^{1/2} \text{ and } F_{2,n}(x) = \sum_{k=m+1}^{\infty} \sqrt{|C_0/M_n|} e^{-(k-M_n^2)^2/(4k)} \frac{|H_k(x)|}{\sqrt{k!}},
\]  
(2.5)
where \( C_0 \) is a suitable constant. The expansion in (2.4) and Lemma 1 below imply that for all
integers \( m \geq M_n^2 \),
\[
\sup_{G([-M_n,M_n])=1} h_G(x) \leq F_{1,n}(x) + F_{2,n}(x).
\]  
(2.6)

Lemma 1. Let \( c_k(G) \) be the coefficients as in (2.4). There exists a positive constant \( C_0 \) such that for all \( G([-M_n,M_n]) = 1 \),
\[
c_k^2(G) \leq \left( \frac{C_0}{M_n^2} \right) e^{-(k-M_n^2)^2/(2k)}, \quad \forall \ k \geq M_n^2.
\]  
(2.7)
Proof of (2.6). For all $G([-M_n, M_n]) = 1$, (2.4) and (2.7) lead to

$$h_G(x) = \sum_{k=1}^m c_k(G) \frac{H_k(x)}{\sqrt{k!}} + \sum_{k=m+1}^\infty c_k(G) \frac{H_k(x)}{\sqrt{k!}}$$

$$\leq \left\{ \sum_{k=1}^m \frac{H_k^2(x)}{k!} \right\}^{1/2} + \sum_{k=m+1}^\infty \sqrt{C_0/M_n} e^{-(k-M_n^2)^2/(4k)} \frac{|H_k(x)|}{\sqrt{k!}}$$

$$= F_{1,n}(x) + F_{2,n}(x).$$

This completes the proof of (2.6).

Lemma 2. Let $F_{1,n}(x)$ and $F_{2,n}(x)$ be the envelope functions defined as in (2.5). Then,

(i) For all positive integers $m$, $\|F_{1,n}\|_2 = m^{1/2}$ and

$$\|F_{1,n}\|_4^4 \leq 9^{m+1}/8. \tag{2.8}$$

(ii) There exists a constant $C_1$ such that for all integers $m$ satisfying $(m-M_n^2)/\sqrt{m} \geq 2t_n$,

$$\|F_{2,n}\|_2 \leq \sqrt{\frac{C_0}{M_n}} \sum_{k=m+1}^\infty e^{-(k-M_n^2)^2/(4k)} \leq C_1 M_n^{1/2} e^{-t_n^2}. \tag{2.9}$$

The upper bound of the fourth moment of the Hermite polynomials in (2.8) will be applied in Lemma 3. Specifically, it is used to prove the uniform square integrability of $h_G$ when $f_G$ is in a neighborhood of $\varphi$ in $\mathcal{F}_n$. This provides sufficient conditions for the equivalence between the Hellinger distance $d(f, \varphi)$ and the Pearson type $\mathcal{L}_2$ distance $\|f/\varphi - 1\|_2$. The detail of the proofs of (2.8) is in Section 6. There, it is shown that

$$\int H_k^4(x)\varphi(x)dx = (k!)^2 \sum_{l=0}^k \binom{k}{l}^2 \left( \frac{2l}{l} \right) \leq (k!)^2 \sum_{l=0}^k \binom{k}{l}^2 2^{2l} = (k!)^2 2^k.$$

Since $\binom{2l}{l} \approx \frac{2^l}{\sqrt{l}}$ by Stirling’s formula, the base 9 in (2.8) is tight.

3 Upper Bound for the Rate of Divergence

Let $\{f_{G_j}, 1 \leq j \leq N_n\}$ be the collection of Gaussian mixtures as in Theorem 1. Define $\psi(x) = 2(x - \log(1+x))$. We have $\psi(x) \geq 0$ and

$$2\ell_n(f_{G_j}, \varphi) = 2n_p(f_{G_j}/\varphi - 1) - n_p\psi(f_{G_j}/\varphi - 1). \tag{3.1}$$

Suppose that we have the following condition,

$$\mathbb{P}_n\psi(f_{G_j}/\varphi - 1) \geq (1 + o_p(1))\|f_{G_j}/\varphi - 1\|^2, \quad \forall 1 \leq j \leq N_n. \tag{3.2}$$
Let $h_j = (f_{G_j}/\varphi - 1)/\|f_{G_j}/\varphi - 1\|_2$. Then, when (3.2) holds,

$$2 \max_{1 \leq j \leq N} \ell_n(f_{G_j}, \varphi) \leq \max_{1 \leq j \leq N} \left\{ 2n \mathbb{P}_n(f_{G_j}/\varphi - 1) - (1 + o_P(1))n\|f_{G_j}/\varphi - 1\|_2^2 \right\}$$

$$= \max_{1 \leq j \leq N} \left\{ 2\sqrt{n}\|f_{G_j}/\varphi - 1\|_2\nu_n(h_j) - (1 + o_P(1))n\|f_{G_j}/\varphi - 1\|_2^2 \right\}$$

(3.3)

with large probability. The supremum of $\ell_n(f, \varphi)$ can be bounded by maximizing the quadratic form of $\sqrt{n}\|f_{G_j}/\varphi - 1\|_2$ in (3.3), which can be written as

$$2 \max_{1 \leq j \leq N} \ell_n(f_{G_j}, \varphi) \leq (1 + o_P(1))\left\{ \max_{1 \leq j \leq N} \nu_n(h_j) \right\}^2.$$  

(3.4)

This approach was taken in Liu and Shao (2003).

**Theorem 2.** Let $\mathcal{F}_n$ be as in (1.3). Suppose (3.2) holds. Then,

$$\sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) = O_P(M_n^2).$$  

(3.5)

**Proof of Theorem 2.** By (3.4), it suffices to bound $\left\{ \max_{1 \leq j \leq N} \nu_n(h_j) \right\}^2$. As in (2.4), we write $h_j$ as $h_j = \sum_{k=1}^{\infty} c_k(G_j)H_k/\sqrt{k!}$. It follows from (2.7) and (2.9) that for integers $m$ satisfying $(m - M_n^2)/\sqrt{m} \geq 2t_n$, we have

$$\mathbb{P} \max_{1 \leq j \leq N} \left| \nu_n\left( \sum_{k=m+1}^{\infty} c_k(G_j)H_k/\sqrt{k!} \right) \right| \leq \sum_{k=m+1}^{\infty} \sqrt{C_0/M_n} e^{-(k-M_n^2)^2/(4k)} \mathbb{P} \left| \nu_n\left( H_k/\sqrt{k!} \right) \right|$$

$$\leq C_1 M_n^{1/2} e^{-t_n^2}.$$  

In the last inequality we used the fact that $\mathbb{P} |\nu_n(H_k/\sqrt{k!})|^2 = 1$. Taking $m$ such that $t_n = \sqrt{\log M_n}$, by the Markov inequality we have $\max_{1 \leq j \leq N} \nu_n\left( \sum_{k=m+1}^{\infty} c_k(G_j)H_k/\sqrt{k!} \right) = o_P(1)$. Since $(a + b)^2 \leq 2(a^2 + b^2)$, by Theorem 1 and (3.4),

$$2 \sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) \leq 2(1 + o(1)) \max_{1 \leq j \leq N} \ell_n(f_{G_j}, \varphi)$$

$$\leq 2(1 + o_P(1)) \left\{ \max_{1 \leq j \leq N} \sum_{k=1}^{m} c_k(G_j)\nu_n(H_k/\sqrt{k!}) \right\}^2 + o_P(1).$$  

(3.6)

Note that

$$\mathbb{P} \left\{ \max_{1 \leq j \leq N} \sum_{k=1}^{m} c_k(G_j)\nu_n(H_k/\sqrt{k!}) \right\}^2 \leq \mathbb{P} \sum_{k=1}^{m} \left\{ \nu_n(H_k/\sqrt{k!}) \right\}^2 = m.$$
Hence by the Markov inequality
\[
\left\{ \max_{1 \leq j \leq N_n} \sum_{k=1}^{m} c_k(G_j) \nu_n(h_j) \right\}^2 = O_P(m).
\]
This, (3.6) and \((m - M_n^2)/\sqrt{m} \geq 2t_n = 2\sqrt{\log M_n}\) imply (3.5).

**Remark 1.** The crucial elements that lead to Theorem 2 are the bounds for the coefficients \(c_k(G)\) in the Hermite polynomial expansion (2.4). They are established in Lemmas 1 and 2. The consequence is that for the expansion of \(\max_{1 \leq j \leq N_n} \nu_n(h_j)\), the remainder beyond the \(m\)-th term is negligible. Because the order of \(m\) is as large as \(M_n^2\), the upper bound of the divergence rate of the NPLRT is \(M_n^2\).

**Theorem 3.** Let \(\mathcal{F}_n\) be as in (1.3). If \(M_n \leq \sqrt{a_0 \log n}\) with \(a_0 < 1/\log 9\), then (3.2) holds. Consequently,
\[
\sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) = O_P\left(M_n^2 \wedge (\log n)\right). \tag{3.7}
\]

It is known that the NPLRT with mixing distributions of unbounded support diverges to infinity in probability (Hartigan, 1985). Jiang and Zhang (2016) proved that the rate of divergence is of equal or smaller order than \((\log n)^2\). Theorem 3 improves upon the rate to \(\log n\), provided that the support range of mixing distribution goes to infinity no faster than \((\log n/\log 9)^{1/2}\). Clearly the divergence rate is slow. Numerical results of the slow divergence of the critical values are demonstrated in Gu, Koenker and Volgushev (2013).

To prove Theorem 3, we need the following lemma which provides sufficient conditions for the equivalence between the Hellinger distance \(d(f, \varphi)\) and the Pearson type \(L_2\) distance \(\|f/\varphi - 1\|_2\).

**Lemma 3.** Let \(\varepsilon_n\) and \(C_n\) be sequences of positive constants satisfying \(\varepsilon_n C_n \to 0\). Suppose that
\[
\sup_{f \in \mathcal{F}_n, d(f, \varphi) \leq \varepsilon_n} \left\| \left( \frac{|f/\varphi - 1|}{\|f/\varphi - 1\|_2} - C_n \right) \right\|_2 \to 0. \tag{3.8}
\]
Then,
\[
\sup_{f \in \mathcal{F}_n, d(f, \varphi) \leq \varepsilon_n} \left| 1 - \frac{2\sqrt{2}d(f, \varphi)}{\|f/\varphi - 1\|_2} \right| \to 0. \tag{3.9}
\]
In particular, condition (3.8) holds when \(\mathcal{F}_n = \{f_G: G([-M_n, M_n]) = 1\}\) with \(M_n \leq \sqrt{a_0 \log n}\) for any \(a_0 < 1/\log 9\).
For each $f$, there exists constants $C_n$ such that $\|((f/\varphi - 1)/\|f/\varphi - 1\|_2 - C_n)\|_2 \to 0$. When (3.8) holds, $|f/\varphi - 1|/\|f/\varphi - 1\|_2$ is said to be uniformly square integrable over $\mathcal{F}_n \cap \{f: d(f, \varphi) \leq \varepsilon_n\}$. Our proof of (3.8) essentially requires the condition that $\int H_m^*(x)\varphi(x)dx \ll n(m!)^2$ for $m = M_n^2(1 + o(1))$ (see proof of Lemma 3). This condition holds iff $M_n < \sqrt{\log n/\log 9}$.

**Proof of Theorem 3.** Let

$$\psi_-(x) = \begin{cases} 
2x - 2\log(1 + x) & x > 0, \\
2x^2 & x \leq 0.
\end{cases} \quad (3.10)$$

Let $\{f_{G_j}, 1 \leq j \leq N_n\}$ be the collection of Gaussian mixtures as in Theorem 1. As $\psi_-(x) \leq \psi(x) = 2(x - \log(1 + x))$, it suffices to prove that

$$\inf_{1 \leq j \leq N_n} \mathbb{P}_n \frac{\psi_-(f_{G_j}/\varphi - 1)}{\|f_{G_j}/\varphi - 1\|_2^2} \geq 1 + o_\varphi(1). \quad (3.11)$$

We have $0 \leq \psi_-(x) \leq x^2$ for all $x$. For $\sigma > 0$ and $x > 0$,

$$\psi_-(\sigma x) = 2 \int_0^{\sigma x} (1 - \frac{1}{1 + t})dt \geq 2\sigma^2 \int_0^{x} \frac{t}{1 + \sigma t}dt \geq \frac{2\sigma^2}{1 + \sigma x} \int_0^{x} t dt = \frac{(\sigma x)^2}{1 + \sigma x}.$$

This implies that for all $x \in \mathbb{R}$,

$$\max_{\tau > 0} \frac{x(x \wedge \tau)}{1 + \sigma \tau} \leq \frac{x^2}{1 + \sigma x} \leq \frac{\psi_-(\sigma x)}{\sigma^2} \leq x^2. \quad (3.12)$$

Then, (3.12) yields

$$0 \leq \frac{h_j(h_j \wedge C_n)}{1 + \|f_{G_j}/\varphi - 1\|_2 C_n} \leq \frac{\psi_-(\|f_{G_j}/\varphi - 1\|_2 h_j)}{\|f_{G_j}/\varphi - 1\|_2^2} = \frac{\psi_-(f_{G_j}/\varphi - 1)}{\|f_{G_j}/\varphi - 1\|_2^2} \leq h_j^2. \quad (3.13)$$

Since $M_n^2 \leq a_0 \log n$ with $a_0 < 1/\log 9$, it follows from Lemma 3 that $2d(f_{G_j}, \varphi)/\|f_{G_j}/\varphi - 1\|_2 = 1 + o(1)$ uniformly. By Theorem 1, we assume without loss of generality that $\|f_{G_j}/\varphi - 1\|_2 \leq \varepsilon_n$. Let $C_n = 1/(\varepsilon_n \log n)$, so that $\|f_{G_j}/\varphi - 1\|_2 C_n \leq \varepsilon_n C_n \to 0$. Then, due to (3.13) and $\mathbb{P} h_j^2 = 1$, (3.11) follows from

$$\max_{1 \leq j \leq N_n} \left| (\mathbb{P}_n - \mathbb{P})(h_j^2 \wedge C_n^2) \right| = o_{\mathbb{P}}(1), \quad (3.14)$$

and

$$\mathbb{P} \left\{ \max_{1 \leq j \leq N_n} \mathbb{P}_n(h_j^2 - C_n^2) \right\} = o(1). \quad (3.15)$$
Since \( \text{var}(h_j^2 \wedge C_n^2) \leq P(h_j^2 \wedge C_n^2)^2 \leq C_n^2 \), the Bernstein’s inequality (van der Vaart and Wellner, 1996, p.102) yields
\[
P \left\{ \max_{1 \leq j \leq N} \left| (P_n - P)(h_j^2 \wedge C_n^2) \right| > t \right\} \leq 2N_n \exp \left\{ -\frac{nt^2}{2C_n^2} \right\}.
\]
Since \( \log N_n \leq n\epsilon_n^2 \) by Theorem 1 and \( n/C_n^2 \leq n\epsilon_n^2 (\log n)^2 \gg n\epsilon_n^2 \), (3.14) holds. For (3.15), (2.6) and (2.8) give that
\[
P \max_{1 \leq j \leq N} P_n(h_j^2 - C_n^2) + 4P \{ (F_{1,n} - C_n/2)^2 + F_{2,n} \}^2 \leq (32/C_n^2)P F_{1,n}^4 + 8P F_{2,n}^2 \leq O(1) 2m/C_n^2 + o(1).
\]
In the last inequality we used (2.9) when \( (m - M_n^2)/\sqrt{m} \geq 2t_n = 2\sqrt{\log M_n} \). The right-hand side above is \( o(1) \) by (6.9) in the proof of Lemma 3. Hence (3.15) also holds. This completes the proof of Theorem 3.

4 Lower Bound for the Rate of Divergence

To derive a lower bound, we may consider a subfamily \( F_n' \subset F_n \). Since \( \sup_{f \in F_n} \ell_n(f, \varphi) \geq \sup_{f \in F_n} \ell_n(f, \varphi) \), any lower bound for \( \sup_{f \in F_n} \ell_n(f, \varphi) \) is a lower bound for \( \sup_{f \in F_n} \ell_n(f, \varphi) \). Probably, the family of two-component Gaussian mixture is the most natural and simplest choice. Let
\[
\mathcal{H} = \{ (1 - p)\varphi(x) + p\varphi(x - \mu) : p \in [0,1], \mu \in \mathbb{R} \}.
\]
The parametric LRT (PLRT) statistic \( \sup_{f \in \mathcal{H}} \ell_n(f, \varphi) \) has been investigated in literature. Hartigan (1985) discovered the PLRT statistic diverges to infinity in probability, and further conjectured that the rate of divergence is \( \log \log n \). Using a result in Bickel and Chernoff (1993), Liu and Shao (2004) confirmed Hartigan’s conjecture, and further proved the asymptotic null distribution. Although the class of mixtures with mixing distributions of unbounded support is considerably larger than the class of two-component mixtures, the support range of the mixing distribution in Theorem 3 increases no faster than \( (\log n/\log 9)^{1/2} \). Hence the rate of \( \log \log n \) cannot serve as a lower bound for the rate of divergence directly. The next theorem shows
that the \( \sqrt{\log n} \) rate is a lower bound if the support range increases no slower than the order of \( \sqrt{\log n} \).

**Theorem 4.** Let \( \mathcal{F}_n \) be as in (1.3). For \( M_n = \sqrt{c_0 \log n} \) with \( c_0 > 0 \),

\[
\Pr \left\{ \sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) \lesssim (\log n)^{1/2} \right\} \to 0. \tag{4.2}
\]

**Proof of Theorem 4.** Let \( 0 = u_0 < u_1 \leq \cdots \leq u_m = \sqrt{c_0 \log n} \) for \( c_0 > 0 \). Let \( \tilde{G} \) be the mixing distribution putting mass \( \pi_j \) at \( u_j \) for \( j = 1, \ldots, m \), and the rest of the mass \( \pi_0 \) at \( 0 \). Similar to Bickel and Chernoff (1993) and Liu and Shao (2004), let \( \pi_j = n^{-1/2} w_j e^{-u_j^2/2} \) with random \( w_j, j = 1, \ldots, m \). For a single observation \( X_i \), the likelihood ratio for \( N(u_j, 1) \) against \( N(0, 1) \) is \( e^{u_j X_i - u_j^2/2} \). The log-likelihood ratio for all data points can be written as

\[
\sum_{i=1}^{n} \log \frac{f_{\tilde{G}}(X_i)}{\varphi(X_i)} = \sum_{i=1}^{n} \log \left( \sum_{j=0}^{m} \pi_j e^{u_j X_i - u_j^2/2} \right) \\
= \sum_{i=1}^{n} \left( 1 + \sum_{j=1}^{m} \pi_j (e^{u_j X_i - u_j^2/2} - 1) \right) \\
= \sum_{i=1}^{n} \left( 1 + \sum_{j=1}^{m} w_j n^{-1/2} (e^{u_j X_i - u_j^2/2} - 1) e^{-u_j^2/2} \right).
\]

Let \( Z_{i,j} = n^{-1/2} (e^{u_j X_i - u_j^2/2} - 1) e^{-u_j^2/2} \). Consider the case where \( \left| \sum_{j=1}^{m} w_j Z_{i,j} \right| \leq 1/2 \). Let \( f(x) = \log(1 + x) - x + x^2 \). Since \( f(0) = 0 \), \( f'(x) \leq 0 \) for \(-1/2 \leq x \leq 0 \) and \( f'(x) > 0 \) for \( 0 < x \leq 1/2 \), \( \log(1 + x) - x \geq -x^2 \) for \( |x| \leq 1/2 \). Thus,

\[
\sum_{i=1}^{n} \log \frac{f_{\tilde{G}}(X_i)}{\varphi(X_i)} \geq \sum_{i=1}^{n} \left\{ \sum_{j=1}^{m} w_j Z_{i,j} - \left( \sum_{j=1}^{m} w_j Z_{i,j} \right)^2 \right\} \\
= \sum_{j=1}^{m} w_j S_j - \sum_{j=1}^{m} \sum_{k=1}^{m} w_j w_k U_{j,k}, \tag{4.3}
\]

where

\[
S_j = \sum_{i=1}^{n} Z_{i,j} = \sum_{i=1}^{n} n^{-1/2} (e^{u_j X_i - u_j^2/2} - 1) e^{-u_j^2/2},
\]

and

\[
U_{j,k} = \sum_{i=1}^{n} Z_{i,j} Z_{i,k} = \frac{1}{n} \sum_{i=1}^{n} (e^{u_j X_i - u_j^2/2} - 1) (e^{u_k X_i - u_k^2/2} - 1) e^{-u_j^2/2 - u_k^2/2}.
\]

10
Let $w_j = \tau \{ \text{sgn}(S_j) + 1 \}/2$ with $\tau > 0$. We have
\[
\sum_{j=1}^{m} w_j S_j - \sum_{j=1}^{m} \sum_{k=1}^{m} w_j w_k U_{j,k} \geq \tau \sum_{j=1}^{m} \max(S_j, 0) - \tau^2 \sum_{j=1}^{m} \sum_{k=1}^{m} |U_{j,k}|.
\]
Since $\mathbb{E}e^{X_i} = e^{t^2/2}$, we have $\mathbb{E}|U_{j,k}| \leq (e^{(u_j+u_k)^2/2-u_j^2/2-u_k^2/2}+3)e^{-u_j^2/2-u_k^2/2} \leq 4e^{-(u_j-u_k)^2/2}$.

Let $u_j = j$. Then,
\[
\mathbb{E} \sum_{j=1}^{m} \sum_{k=1}^{m} |U_{j,k}| \leq 4 \sum_{j=1}^{m} \sum_{k=1}^{m} e^{-(j-k)^2/2} \leq C_1m.
\]
Because $\mathbb{E}(e^{u_j X_i - u_j^2/2} - 1) e^{-u_j^2/2} = 0$ and $\mathbb{E}((e^{u_j X_i - u_j^2/2} - 1) e^{-u_j^2/2})^2 = 1 - e^{-u_j^2}$, $S_j \rightarrow N(0, 1)$ as $j \rightarrow \infty$. Then, there exists a small constant $\tau$ such that
\[
\mathbb{E}\left\{ \tau \sum_{j=1}^{m} \max(S_j, 0) - \tau^2 \sum_{j=1}^{m} \sum_{k=1}^{m} |U_{j,k}| \right\} \geq \tau C_2m \mathbb{E}(N(0, 1))_+ - \tau^2 C_1m \geq C_3m.
\]
Because the order of $m$ is $\sqrt{\log n}$, we find that
\[
\sum_{i=1}^{n} \log \frac{f_{\hat{G}}(X_i)}{\varphi(X_i)} \gtrsim \sqrt{\log n}
\]
with large probability.

It remains to verify that $\left| \sum_{j=1}^{m} w_j Z_{i,j} \right| \leq 1/2$ with large probability. It suffices to consider $\max |X_i| \leq \sqrt{2 \log n}$ as it holds with large probability. We have,
\[
\left| \sum_{j=1}^{m} w_j Z_{i,j} \right| = \sum_{j=1}^{m} w_j n^{-1/2} (e^{u_j X_i - u_j^2/2} - 1) e^{-u_j^2/2}
\leq 2\tau n^{-1/2} \sum_{j=1}^{m} e^{u_j \sqrt{2 \log n} - u_j^2}
\leq 2\tau \sum_{j=1}^{m} e^{-(u_j - \sqrt{2 \log n/2})^2} \leq C_4 \tau.
\]
The last inequality holds because for $u_j = j$ the summands decrease faster than geometric rate from center. Taking a constant $\tau \leq C_4/2$ gives that $\left| \sum_{j=1}^{m} w_j Z_{i,j} \right| \leq 1/2$. This completes the proof of Theorem 4.

In the proof we set $u_j = j$, so the number of support points is of order $\sqrt{\log n}$. It is known that the NPMLE is a mixture of at most $n$ components (Lindsay, 1995). However, putting
denser equal-spaced support points in support range does not improve the lower bound in our analysis.

**Remark 2.** It is unclear whether the exact rate of divergence of the NPLRT is $\sqrt{\log n}$ or $\log n$, or a rate between them. Our analyses for the upper and lower bounds are very different. The proof of the upper bound is based on the expansion of the standardized likelihood ratio in the Hermite polynomial basis in (2.4), which leads to the use of the fourth moment condition on the envelope function $F_{1,n}$ as we remarked below the statement of Lemma 3. This seems to be cruder than the lower bound analysis. However, we are unable to use the more natural expansion in the lower bound calculation to derive an upper bound as the magnitude of $w_j$ is hard to control. In any case, little is known about the NPMLE, in spite of Lindsay (1995), Genovese and Wasserman (2000), Ghosal and van der Vaart (2001), Zhang (2009) and other studies in the literature.

5 Discussion

5.1 Implications of the upper bound

The divergence rate of the NPLRT was proved to be bounded by $(\log n)^2$ in Jiang and Zhang (2016) by a large deviation inequality:

$$P_{H_0}\left\{ \sum_{i=1}^{n} \log \frac{\hat{f}_n(X_i)}{\varphi(X_i)} \geq n\varepsilon_n^2 \right\} \to 0. \quad (5.1)$$

This has an implication of the two-component testing problem:

$$H_0: f(x) = \varphi(x) \quad \text{against} \quad H_1^{(n)}: f(x) = (1 - p_n)\varphi(x) + p_n\varphi(x - \mu_n). \quad (5.2)$$

The alternative says only a small fraction of normal means is nonzero, and they have the same value. In the sparse case, namely, $1/2 < \beta < 1$, let $p_n = n^{-\beta}$ and $\mu_n = \sqrt{2r\log n}$ be calibration. Let $\rho^*(\beta) = \beta - 1/2$ if $1/2 < \beta \leq 3/4$, and $\rho^*(\beta) = (1 - \sqrt{1 - \beta})^2$ otherwise. The detection limit of (5.2) is given by $\rho^*(\beta)$ (Ingster, 1999; Donoho and Jin, 2004). The NPLRT separates the null and the alternative asymptotically in the “detectable region”, that is, $r > \rho^*(\beta)$ (Jiang and Zhang, 2016).

The PLRT for contiguous alternative hypothesis was studied in Azaïs, Gassiat and Mercadier (2006). This is the dense case of (5.2), where $0 < \beta \leq 1/2$ under $p_n = n^{-\beta}$. In the dense case, $\mu_n$ is calibrated by $\mu_n = n^{-r}$. The detectable region is $r < \rho^*(\beta)$ where $\rho^*(\beta) = 1/2 - \beta$. 
When $n^{1/2}p_n\mu_n \to \gamma \in \mathbb{R}$ and $\mu_n \to \mu_0 \in \mathbb{R}$, the asymptotic power of the PLRT is equal to the asymptotic level (Azaïs, Gassiat and Mercadier, 2006). This implies that in the case where $r = (1 + o(1))\rho^*(\beta)$, the PLRT cannot distinguish the null from the alternative asymptotically.

We provide a result which says the NPLRT is consistent in the interior of the detectable region.

**Theorem 5.** Consider the testing problem (5.2) where $0 < \beta \leq 1/2$ under $p_n = n^{-\beta}$. Let $\mu_n = n^{-r}$. Let $q(n, \alpha)$ be the critical value such that $P_{H_0}(\ell_n(\hat{f}_n, \varphi) > q(n, \alpha)) = \alpha$. The rejection region is $\ell_n(\hat{f}_n, \varphi) > q(n, \alpha)$. Then

$$P_{H_0}(\text{NPLRT in (1.2) rejects } H_0) \to 1, \quad n \to \infty$$

if and only if $r < \rho^*(\beta)$ where $\rho^*(\beta) = 1/2 - \beta$.

If we let $\alpha \to 0$, then the sum of Type I and Type II errors tends to zero. So the NPLRT separates the null and the alternative asymptotically in the detectable region.

### 5.2 Simulations

We provide some simulation results to compare the NPLRT and the PLRT. Because the log log $n$ rate of divergence is very slow, the asymptotic distribution is not directly applicable in computing the critical values of the PLRT under the null. In our simulations, both the critical values of the PLRT and the NPLRT under the null are simulated.

We first considered (5.2). We set $(n, p_n) = (1000, 0.005)$. The corresponding sparse parameter under $p_n = n^{-\beta}$ is $\beta = 0.767$. We let the amplitude parameter $\mu_n$ range from 1.5 to 4 with an increment of 0.25. We set the significance level $\alpha = 0.05$. Table 1 displays the powers of the PLRT and the NPLRT under the null are simulated.

We next considered testing $H_0$ against the Gaussian hierarchical model. Under the alternative, the non-standard normal observations are from $N(\mu_i, 1)$ where $\mu_i \sim N(0, \tau^2)$. We set $(n, p_n) = (1000, 0.005)$ and (1000, 0.01). We let $\tau$ range from 1 to 4.5 with an increment of 0.5. The results are reported in Table 2. In this simulation, the NPLRT yields much stronger performance.

### 5.3 Other mixtures

The methods to derive the upper bound is applicable to multivariate Gaussian location mixtures. For independent bivariate normal distribution with unit variances, the Gaussian
Table 1: Powers for (5.2) at level α = 0.05. \((n, p_n) = (1000, 0.005)\).

mixtures have the expansion

\[
f_G(x, y) = \varphi(x, y) \sum_{j=0}^{\infty} \sum_{k=0}^{\infty} \mu_{j,k}(G) \frac{H_j(x) H_k(y)}{j! k!},
\]

where \(\varphi(x, y) = \exp(-x^2/2 - y^2/2)/(2\pi)\) and \(\mu_{j,k}(G) = \int u^j v^k dG(u, v)\) is the \((j, k)\)-th moment of \(G\). The generalized score function \(h_G(x, y) \equiv (f_G(x, y)/\varphi(x, y) - 1)/\|f_G/\varphi - 1\|_2\) is expanded by

\[
h_G(x, y) = \sum_{(j,k) \neq (0,0)} c_{j,k}(G) \frac{H_j(x) H_k(y)}{\sqrt{j! k!}},
\]

where \(c_{j,k}(G) = \{\mu_{j,k}(G)/\sqrt{j! k!}\}/\{\sum_{(j,k) \neq (0,0)} \mu_{j,k}^2(G)/(j! k!)\}^{1/2}\). Let

\[
F_{1,n}(x, y) = \left\{ \sum_{j=1}^{m_1} \sum_{k=1}^{m_2} \frac{1}{j! k!} H_j^2(x) H_k^2(y) \right\}^{1/2}.
\]

By analysis parallel to Lemma 1 and 2, it can be shown that the cutoffs are \(m_1 \approx M_2\) and \(m_2 \approx M_3\). Similar analysis can be carried out in general fixed dimension.

The methods is potentially applicable to Poisson mixtures \(p_G(z) = \int z^e e^{-z}/x! dG(z)\). We test \(H_0: z = z_0\). The generalized score function can be expanded by the Charlier polynomials (Azaïs, Gassiat and Mercadier, 2009),

\[
g_G(x) = \frac{p_G(x)/p_0(x) - 1}{\|p_G/p_0 - 1\|_2} = \sum_{k=1}^{\infty} b_k(G) C_k(x),
\]

(5.6)
where \( b_k(G) = \{m_k(G)/(k!z_0^k)\}/\{\sum_{j=1}^{\infty} m_j^2(G)/(j!z_0^j)\}\}^{1/2}, m_k(G) = E_G(z - z_0)^k \) and
\[
C_k(x) = z_0^k \frac{d^k}{dz^k} \left( \frac{z}{z_0} \right)^x e^{-z + z_0} \Big|_{z = z_0}.
\]

6 Proofs

Proof of Theorem 1. First of all, \( \sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) \leq n\varepsilon_n^2 \) follows directly from Theorem 1 of Jiang and Zhang (2016).

Let \( \mathcal{F}_n = \{f_{G}: G([-M_n, M_n]) = 1\}. \) Since \( \varphi \in \mathcal{F}_n, \) we have \( \ell_n(f_{\varphi}, \varphi) \geq 0 \geq -n\varepsilon_n^2. \)

By the proof of Theorem 1 of Zhang (2009), the nonparametric MLE over \( \mathcal{F}_n \) converges: \( P\{d(\hat{f}_{\varphi}, f_{\varphi}) \geq \varepsilon_n\} \to 0, \) where \( \varepsilon_n \sim (\log n)/\sqrt{n}. \) For any semi-distance \( d_0, \) let \( \text{Ball}(h_0, \eta, d_0) = \{h: d_0(h, h_0) < \eta\} \) be the ball of radius \( \eta \) around \( h_0. \) We consider the \( \eta \)-cover of \( \mathcal{F}_n \cap \{f: d(f, \varphi) \leq \varepsilon_n\} \) for \( \eta = 1/n^3. \) It follows from Lemma 2 of Zhang (2009) that there exists \( \{f_{G_j}, 1 \leq j \leq N_n\} \subset \mathcal{F}_n \cap \{f: d(f, \varphi) \leq \varepsilon_n\} \) with \( \log N_n \leq n\varepsilon_n^2 \) such that for \( M_n \sim \sqrt{\log n}, \)
\[
\mathcal{F}_n \cap \{f: d(f, \varphi) \leq \varepsilon_n\} \subset \bigcup_{j=1}^{N_n} \text{Ball}(f_{G_j}, 1/n^3, \|\cdot\|_{\infty, M_n}),
\]
where \( \|h\|_{\infty, M} = \sup_{|x| \leq M} |h(x)| \) is the supreme norm in bounded intervals.

Proposition 2 of Jiang and Zhang (2009) asserts that for all \( i = 1, \ldots, n, \) \( \hat{f}_n(X_i) \geq 1/(\sqrt{2\pi}n). \) Then, for \( f_{G_j} \) such that \( \|\hat{f}_n - f_{G_j}\|_{\infty, M_n} \leq 1/n^3, \) we have
\[
\left| \sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) - \ell_n(f_{G_j}, \varphi) \right| = \left| \sum_{i=1}^{n} \left( \log f_{G_j}(X_i) - \log f(X_i) \right) - \sum_{i=1}^{n} \left( \log \hat{f}_n(X_i) - \log f(X_i) \right) \right| \\
\leq \left| \sum_{i=1}^{n} \log \left( 1 + \frac{\|f_{G_j} - \hat{f}_n\|_{\infty, M_n}}{f_n(X_i)} \right) \right| \\
\leq \sqrt{2\pi}e/n.
\]
This and \( \sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) \geq \chi_1^2 \) imply that \( \sup_{f \in \mathcal{F}_n} \ell_n(f, \varphi) = (1 + \eta_n) \sup_{1 \leq j \leq N_n} \ell_n(f_{G_j}, \varphi) \) with large probability, where \( |\eta_n| \sim 1/n. \)  

Proof of Lemma 1. We use \( C_0 \) to denote a universal constant which may take different values from one appearance to another.
Let \( m_0 \) be an integer satisfying \( 2(m_0 - 1) < M_n^2 \leq 2m_0 \). For \( j \leq m_0 \), \( \mu_{2m_0}^2(G) \leq (M_n^2)^{2m_0 - 2j}\mu_{2j}^2(G) \). So

\[
\sum_{j=1}^{m_0} \frac{\mu_j^2(G)}{j!} \geq \sum_{j=1}^{m_0} \frac{\mu_{2j}^2(G)}{(2j)!} \geq \frac{\mu_{2m_0}^2(G)}{(2m_0)!} \sum_{j=1}^{m_0} \frac{(2m_0)!}{(2j)!((M_n^2)^{2m_0 - 2j})}. \quad (6.1)
\]

By Stirling’s formula,

\[
\sum_{j=1}^{m_0} \frac{(2m_0)!}{(2j)!((M_n^2)^{2m_0 - 2j})} = \frac{(2m_0)!}{M_n^{4m_0}} \sum_{j=1}^{m_0} (M_n^2)^{2j} \geq \frac{\sqrt{2\pi M_n^2}}{M_n^{4m_0}} \left( M_n^2 e \right)^{2m_0} (C_0 e M_n^2) \geq \frac{M_n}{C_0}. \quad (6.2)
\]

Since \( \mu_k^2(G) \leq (2m_0)^{k-2m_0} \mu_{2m_0}^2(G) \) for \( k \geq 2m_0 \), it follows from (6.1) and (6.2) that

\[
\epsilon_k^2(G) \leq \frac{\mu_k^2(G)/k!}{(M_n/C_0) \mu_{2m_0}^2(G)/(2m_0)!} \leq \left( \frac{C_0}{M_n} \right) (2m_0)^{k-2m_0} (2m_0)!/k!.
\]

Since \( (2m_0)^{k-2m_0} (2m_0)!/k! = \prod_{j=1}^{k-2m_0} (1 - j/(2m_0 + j)) \leq e^{-(k-2m_0)^2/(2k)} \), (2.7) follows.

**Proof of Lemma 2.** (i) First of all, \( \|F_{1,n}\|_2^2 = m \) follows directly from \( \int H_j(x)H_k(x)\varphi(x)dx = k!I\{j = k\} \). We include a proof since it leads to the proof of (2.8). Due to

\[
H_k(x) = (-1)^k e^{-x^2/2} \frac{d^k}{dt^k} e^{-t^2/2} \Big|_{t=x} = e^{x^2/2} \frac{d^k}{du^k} e^{-(x-u)^2/2} \Big|_{u=0} = \frac{d^k}{du^k} e^{xu-u^2/2} \Big|_{u=0},
\]

the second moment of the Hermite polynomials can be computed via

\[
\int H_j(x)H_k(x)\varphi(x)dx = \frac{\partial^j}{\partial w^j} \frac{\partial^k}{\partial v^k} \int e^{xu-u^2/2+xv-v^2/2} \varphi(x)dx \Big|_{u=v=0} = \frac{\partial^j}{\partial w^j} \frac{\partial^k}{\partial v^k} e^{uw} \Big|_{u=v=0} = k!I\{j = k\}.
\]

This gives the orthogonality. Similarly, the fourth moment of the Hermite polynomials can be
computed via
\[
\int \prod_{j=1}^{4} H_{k_j}(x) \varphi(x) dx = \left( \prod_{j=1}^{4} \frac{\partial^{k_j}}{\partial u_j^{k_j}} \right) \int \exp \left\{ \sum_{1 \leq j \leq 4} (x u_j - u_j^2/2) \right\} \varphi(x) dx \bigg|_{u_1=u_2=u_3=u_4=0}
\]
\[
= \left( \prod_{j=1}^{4} \frac{\partial^{k_j}}{\partial u_j^{k_j}} \right) \exp \left\{ u_1 u_2 + u_1 u_3 + u_1 u_4 + u_2 u_3 + u_2 u_4 + u_3 u_4 \right\} \bigg|_{u_1=u_2=u_3=u_4=0}. \quad (6.3)
\]
Let \( m = (k_1 + k_2 + k_3 + k_4)/2 \). Assume that \( m \) is an integer as the right-hand side above is zero otherwise. Let \( k_1 \geq k_2 \geq k_3 \geq k_4 \). We have \( k_4 + k_3 \leq m \) and
\[
\int \prod_{j=1}^{4} H_{k_j}(x) \varphi(x) dx
\]
\[
= \frac{1}{m!} \left( \prod_{j=1}^{4} \frac{\partial^{k_j}}{\partial u_j^{k_j}} \right) \left( \sum_{1 \leq j_1 < j_2 \leq 4} u_{j_1} u_{j_2} \right)^m \bigg|_{u_1=u_2=u_3=u_4=0}
\]
\[
= k_4! \left( \frac{m}{k_4} \right) \left( \prod_{j=1}^{3} \frac{\partial^{k_j}}{\partial u_j^{k_j}} \right) \left( \sum_{1 \leq j \leq 3} u_{j} \right)^{k_4} \left( \sum_{1 \leq j_1 < j_2 \leq 3} u_{j_1} u_{j_2} \right)^{m-k_4} \bigg|_{u_1=u_2=0}
\]
\[
= \sum_{l=0}^{k_4} \frac{k_3!}{(m-k_4)!} \binom{k_4}{l} \binom{m-k_4}{k_3-l} \left( \prod_{j=1}^{3} \frac{\partial^{k_j}}{\partial u_j^{k_j}} \right) (u_1 + u_2)^{k_4-l+(k_3-l)} (u_1 u_2)^{m-k_4-(k_3-l)} \bigg|_{u_1=u_2=0}
\]
\[
= \sum_{l=0}^{k_4} \frac{k_3!}{(m-k_4)!} \binom{k_4}{l} \binom{m-k_4}{k_3-l} \binom{k_4+k_3-2l}{k_2-(m-k_4-k_3+l)} k_2! k_1! \bigg|_{u_1=u_2=0}
\]
\[
= \sum_{l=0}^{k_4} \frac{k_1! k_2! k_3! k_4! (k_4+k_3-2l)!}{l!(k_4-l)!(k_3-l)! (m-k_4-k_3+l)!(m-k_2-l)!(m-k_1-l)!}. \quad (6.4)
\]
The above quantity is counted as zero when \( m < k_1 + l \). In particular, for \( k_4 = k_3 = k_2 = k_1 \),
\[
\int H_k^1(x) \varphi(x) dx = (k!)^2 \sum_{l=0}^{k} \binom{k}{l}^2 \binom{2k-2l}{k-l}
\]
\[
= (k!)^2 \sum_{l=0}^{k} \binom{k}{l}^2 \binom{2k-2l-1}{k-l}
\]
\[
= (k!)^2 \sum_{l=0}^{k} \binom{k}{l}^2 \binom{2l+1}{l}
\]
\[
\leq (k!)^2 \sum_{l=0}^{k} \binom{k}{l}^2 2^{2l} \leq (k!)^2 \left\{ \sum_{l=0}^{k} \binom{k}{l}^2 \right\}^2 = (k!)^2 g^k. \quad (6.5)
\]
It follows that
\[
\|F_{1,n}\|_4^4 = \int \left\{ \sum_{k=1}^{m} \left( \frac{H_k(x)}{\sqrt{k!}} \right)^2 \varphi(x) \right\}^2 dx \\
= \int \sum_{k=1}^{m} \left( \frac{H_k(x)}{\sqrt{k!}} \right)^4 \varphi(x) dx = \sum_{k=1}^{m} \|H_k\|_4^4 \leq \sum_{k=1}^{m} 9k \leq 9^{m+1}/8.
\]

Since \(\left(\frac{2l}{l}\right) \approx \frac{2^{\frac{l}{2}}}{\sqrt{l}}\), the base 9 in (6.5) is tight.

(ii) Let \(y = (x - M_n^2)/\sqrt{x}\). For \(x > m\), we have
\[
dx = 2 \frac{dy}{x - 1/2 + M_n^2 x^{-3/2}} = \frac{(2y + 2M_n^2/x^{1/2})dy}{1 + M_n^2/x} \\
\leq (2y + 2M_n^2/x^{1/2})dy \leq (2y + M_n)dy.
\]
When \(x \geq m\), \(y = (x - M_n^2)/\sqrt{x} \geq (m - M_n^2)/\sqrt{m} \geq 2t_n\). By the triangle inequality and (6.6),
\[
\|F_{2,n}\|_2 \leq \sqrt{C_0/M_n} \sum_{k=m+1}^{\infty} e^{-(k-M_n^2)^2/(4k)} \\
\leq \sqrt{C_0/M_n} \int_m^{\infty} e^{-(x-M_n^2)^2/(4x)} dx \\
\leq \sqrt{C_0/M_n} \int_{2t_n}^{\infty} e^{-y^2/4}(2y + M_n)dy \\
\leq \sqrt{C_0/M_n} (4e^{-t_n^2} + M_ne^{-t_n^2} \int_0^{\infty} e^{-y^2/4}dy) = C_1 M_n^{1/2} e^{-t_n^2}.
\]
This completes the proof of (2.9).

**Proof of Lemma 3.** Since
\[
\|\sqrt{f/\varphi - 1}\|_2^2 = \int (\sqrt{f/\varphi - 1})^2 \varphi dx = \int (\sqrt{f} - \sqrt{\varphi})^2 dx = 2d^2(f, \varphi),
\]
we have
\[
\sup_{f \in \mathcal{F}_n, d(f, \varphi) \leq \varepsilon_n} \left| 1 - 2\sqrt{2}d(f, \varphi) \right| \leq \sup_{f \in \mathcal{F}_n, d(f, \varphi) \leq \varepsilon_n} \left\| \frac{f}{\varphi - 1} - \frac{2(\sqrt{f/\varphi} - 1)}{\|f/\varphi - 1\|_2} \right\|_2
\]
by the triangle inequality. Let \(h = (f/\varphi - 1)/\|f/\varphi - 1\|_2\). Then, (3.8), (6.7) and \(\varepsilon_n C_n \to 0\)
imply that
\[
\sup_{f \in F_n, d(f, \phi) \leq \epsilon_n} \left\| \frac{f}{\phi} - 1 \right\|_2 - \frac{2(\sqrt{f/\phi} - 1)}{\left\| f/\phi - 1 \right\|_2} \leq \sup_{f \in F_n, d(f, \phi) \leq \epsilon_n} \left\| \frac{\sqrt{f/\phi} - 1}{\sqrt{f/\phi} + 1} h \right\|_2 = \sup_{f \in F_n, d(f, \phi) \leq \epsilon_n} \left\| \frac{\sqrt{f/\phi} - 1}{\sqrt{f/\phi} + 1} (|h| - C_n + C_n) \right\|_2 \leq \sup_{f \in F_n, d(f, \phi) \leq \epsilon_n} \left\{ \left\| (|h| - C_n)_+ \right\|_2 + \sqrt{2\epsilon_n C_n} \right\} \to 0.
\]

It remains to verify (3.8) for the specific \( M_n \). For bounded \( M_n \), (3.8) follows from the fact that \( F_{1,n} + F_{2,n} \) for some fixed \( m \) is an \( L_2 \) envelope function. Assume \( M_n \to \infty \). Let \( C_n = 1/(\epsilon_n \log n) \). Since \( (F_{1,n} - C_n)_+ \leq F_{1,n}/C_n \), by Lemma 2, when \( (m - M_n^2)/\sqrt{m} \geq 2t_n = 2\sqrt{\log M_n} \),

\[
\sup_{f \in F_n, d(f, \phi) \leq \epsilon_n} \left\| \frac{|f/\phi - 1|}{\left\| f/\phi - 1 \right\|_2} - C_n \right\|_2 \leq \sup_{f \in F_n, d(f, \phi) \leq \epsilon_n} \left\| (F_{1,n} - C_n)_+ \right\|_2 + \left\| F_{2,n} \right\|_2 \leq \left\| F_{1,n} \right\|^2_2/C_n + o(1) \leq O(1)3^m/C_n + o(1).
\]

Thus, when \( M_n^2 \leq a_0 \log n \) with \( a_0 < 1/\log 9 \),

\[
\log(3^{2m}/C_n^2) = \log((\log n)^2 \epsilon_n^2 9^m) \leq \log((\log n)^4 9^m/n) + O(1) \leq (\log n)(1 + o(1))a_0 \log 9 - 1 + O(\log \log n) \to -\infty. \tag{6.9}
\]

This completes the proof of Lemma 3.

\[\square\]

**Proof of Theorem 5.** Let \( G^{(n)} = (1 - p_n)\delta_0 + p_n\delta_{\mu_n} \) where \( \delta_{\mu} \) is the probability distribution giving its entire mass to \( \mu \). Using Theorem 2 of Jiang and Zhang (2016), it remains to prove that \( nd^2(\varphi, f_{G^{(n)}})/(\log n)^2 \to \infty \) if and only if \( r < 1/2 - \beta \). Note that \( f_{G^{(n)}}(x) = \)
\( (1 - p_n)\varphi(x) + p_n\varphi(x - \mu_n) \). We divide the Hellinger distance into two parts:

\[
2d^2(\varphi, f_{G(n)}) = \int \left( \sqrt{\varphi(x)} - \sqrt{(1 - p_n)\varphi(x) + p_n\varphi(x - \mu_n)} \right)^2 dx
\]

\[
= \int \left( 1 - \sqrt{1 - n^{-\beta} + n^{-\beta} \exp(x\mu_n - \mu_n^2/2)} \right)^2 \varphi(x) dx
\]

\[
= \int_{-\infty}^{\beta \log n + \mu_n/2} + \int_{\beta \log n + \mu_n/2}^{+\infty} \frac{\beta}{n} \log n \varphi(x) dx
\]

\[
\triangle = I_1 + I_2. \tag{6.10}
\]

We first calculate \( I_1 \). When \( x < (\beta/\mu_n) \log n + \mu_n/2 \), the Taylor series gives that

\[
\sqrt{1 - n^{-\beta} + n^{-\beta} \exp(x\mu_n - \mu_n^2/2)} = 1 - \frac{1}{2}(1 + o(1)) n^{-\beta} \left\{ 1 - \exp \left( x\mu_n - \frac{\mu_n^2}{2} \right) \right\}.
\]

Then,

\[
I_1 = (1 + o(1)) \int_{-\infty}^{\beta \log n + \mu_n/2} \frac{1}{4} n^{-2\beta} \left\{ 1 - \exp \left( x\mu_n - \frac{\mu_n^2}{2} \right) \right\}^2 \varphi(x) dx
\]

\[
= (1 + o(1)) \frac{1}{4} n^{-2\beta} \int_{-\infty}^{\beta \log n + \mu_n/2} \left\{ 1 - 2 \exp \left( x\mu_n - \frac{\mu_n^2}{2} \right) + \exp(2x\mu_n - \mu_n^2) \right\} \varphi(x) dx
\]

\[
\triangle = (1 + o(1))(I_3 + I_4 + I_5). \tag{6.11}
\]

Here

\[
I_3 = \frac{1}{4} n^{-2\beta} \Phi \left( \frac{\beta}{\mu_n} \log n + \frac{\mu_n}{2} \right).
\]

The cross term is

\[
I_4 = -\frac{1}{2} n^{-2\beta} \int_{-\infty}^{\beta \log n + \mu_n/2} \exp \left( x\mu_n - \frac{\mu_n^2}{2} \right) \varphi(x) dx
\]

\[
= -\frac{1}{2} n^{-2\beta} \Phi \left( \frac{\beta}{\mu_n} \log n - \frac{\mu_n}{2} \right).
\]

Some calculations show that

\[
I_5 = \frac{1}{4} n^{-2\beta} \int_{-\infty}^{\beta \log n + \mu_n/2} \exp(2x\mu_n - \mu_n^2) \varphi(x) dx
\]

\[
= \frac{1}{4} n^{-2\beta} \exp(n^{-2r}) \Phi \left( \frac{\beta}{\mu_n} \log n - \frac{3}{2} \mu_n \right).
\]
Putting $I_3$, $I_4$ and $I_5$ together, we obtain
\[
I_3 + I_4 + I_5
= \frac{1}{4} n^{-2\beta} \left\{ \Phi \left( \frac{\beta}{\mu_n} \log n + \frac{\mu_n}{2} \right) - 2\Phi \left( \frac{\beta}{\mu_n} \log n - \frac{\mu_n}{2} \right) + \exp(\mu_n n^r) \Phi \left( \frac{3\mu_n}{2} - \frac{\beta}{\mu_n} \log n \right) \right\}
= \frac{1}{4} (1 + o(1)) n^{-2\beta} \left( \exp(\mu_n n^r) - 1 \right)
= \frac{1}{4} (1 + o(1)) n^{-2r-2\beta}.
\]
This and (6.11) give that
\[
I_1 \gg (\log n)^2 / n \quad \text{iff} \quad r < \frac{1}{2} - \beta. \tag{6.12}
\]

The analysis $I_2$ is easier. When $x \geq (\beta/\mu_n) \log n + \mu_n/2$, the main term in the square root is $n^{-\beta} \exp(x\mu_n - \mu_n^2/2)$. So
\[
I_2 &= \int_{\frac{\mu_n}{n} \log n + \frac{\mu_n}{2}}^{+\infty} \left( 1 - \sqrt{1 - n^{-\beta} + n^{-\beta} \exp(x\mu_n - \mu_n^2/2)} \right)^2 \varphi(x) dx \\
&= O(1) n^{-\beta} \int_{\frac{\mu_n}{n} \log n + \frac{\mu_n}{2}}^{+\infty} \exp \left( x\mu_n - \frac{\mu_n^2}{2} \right) \varphi(x) dx \\
&= O(1) n^{-\beta} \Phi(n^{-r}/2 - \beta n^r \log n) \\
&\ll (\log n)^2 / n. \tag{6.13}
\]
The last step is due to $\Phi(-x) = (1 + o(1)) \varphi(x)/x$.

Combining $2d^2(\varphi, f_{G(n)}) = I_1 + I_2$, (6.12) and (6.13), we have that $d^2(\varphi, f_{G(n)}) \gg (\log n)^2 / n$ if and only if $r < 1/2 - \beta$.

\[\square\]
