We prove a new concentration inequality for U-statistics of order two for uniformly ergodic Markov chains. Working with bounded and π-canonical kernels, we show that we can recover the convergence rate of Arcones and Giné who proved a concentration result for U-statistics of independent random variables and canonical kernels. Our result allows for a dependence of the kernels \( h_{i,j} \) with the indexes in the sums, which prevents the use of standard blocking tools. Our proof relies on an inductive analysis where we use martingale techniques, uniform ergodicity, Nummelin splitting and Bernstein’s type inequality.

Assuming further that the Markov chain starts from its invariant distribution, we prove a Bernstein-type concentration inequality that provides sharper convergence rate for small variance terms.

Keywords: U-statistics; Markov chains; Concentration inequality

1. Introduction

Concentration of measure has been intensely studied during the last decades since it finds application in large span of topics such as model selection (see [33] and [31]), statistical learning (see [9]), online learning (see [44]) or random graphs (see [10] and [15]). Important contributions in this field are those concerning U-statistics. A U-statistic of order \( m \) is a sum of the form

\[
\sum_{1 \leq i_1 < \cdots < i_m \leq n} h_{i_1,\ldots,i_m}(X_{i_1},\ldots,X_{i_m}),
\]

where \( X_1,\ldots,X_n \) are independent random variables taking values in a measurable space \((E,\Sigma)\) (with \( E \) Polish) and with respective laws \( P_i \) and where \( h_{i_1,\ldots,i_m} \) are measurable functions of \( m \) variables \( h_{i_1,\ldots,i_m} : E^m \to \mathbb{R} \).

One important exponential inequality for U-statistics was provided by [4] using a Rademacher chaos approach. Their result holds for bounded and canonical (or degenerate) kernels, namely satisfying for all \( i_1,\ldots,i_m \in [n] := \{1,\ldots,n\} \) with \( i_1 < \cdots < i_m \) and for all \( x_1,\ldots,x_m \in E \),

\[
\|h_{i_1,\ldots,i_m}\|_\infty < \infty \quad \text{and} \quad \forall j \in [1,n], \ E_X h_{i_1,\ldots,i_m}(x_1,\ldots,x_{j-1},X_j,x_{j+1},\ldots,x_m) = 0.
\]

They proved that in the degenerate case, the convergence rates for U statistics are expected to be \( n^{m/2} \). Relying on precise moment inequalities of Rosenthal type, Giné, Latala and Zinn in [21] improved the result from [4] by providing the optimal four regimes of the tail, namely Gaussian, exponential, Weibull of orders 2/3 and 1/2. In the specific case of order 2 U-statistics, Houdré and Reynaud-Bouret in [26] recovered the result from [21] by replacing the moment estimates by martingales type inequalities,
giving as a by-product explicit constants. When the kernels are unbounded, it was shown that some results can be extended provided that the random variables \( h_{i_1, \ldots, i_m}(X_{i_1}, \ldots, X_{i_m}) \) have sufficiently light tails. One can mention [17, Theorem 3.26] where an exponential inequality for U-statistics with a single Banach-space valued, unbounded and canonical kernel is proved. Their approach is based on a decoupling argument originally obtained by [11] and the tail behavior of the summands is controlled by assuming that the kernel satisfies the so-called weak Cramér condition. It is now well-known that with heavy-tailed distribution for \( h_{i_1, \ldots, i_m}(X_{i_1}, \ldots, X_{i_m}) \) we cannot expect to get exponential inequalities anymore. Nevertheless working with kernels that have finite \( p \)-th moment for some \( p \in (1, 2] \), Joly and Lugosi in [28] construct an estimator of the mean of the U-process using the median-of-means technique that performs as well as the classical U-statistic with bounded kernels.

All the above mentioned results consider that the random variables \((X_i)_{i \geq 1}\) are independent. This condition can be prohibitive for practical applications since modeling of real phenomena often involves some dependence structure. The simplest and the most widely used tool to incorporate such dependence is Markov chain. One can give the example of Reinforcement Learning (see [42]) or Biology (see [41]). Recent works provide extensions of the classical concentration results to the Markovian settings as [18, 27, 35, 1, 9]. The asymptotic behaviour of U-statistics in the Markovian setup has already been investigated by several papers. We refer to [6] where the authors proved a Strong Law of Large Numbers and a Central Limit Theorem proved for U-statistics of order 2 using the renewal approach based on the splitting technique. One can also mention [16] regarding large deviation principles. However, there are only few results for the non-asymptotic behaviour of tails of U-statistics in a dependent framework. The first results were provided in [7] and [24] where exponential inequalities for U-statistics of order \( m \geq 2 \) of time series under mixing conditions are proved. Those works were improved by [39] where a Hoeffding-type inequality for V and U statistics is provided under conditions on the time dependent process that are easier to check in practice. In Section 3.4, we describe in details the result of [39] and the differences with our work. Let us point out that all the above mentioned works regarding non-asymptotic tail bound for U-statistics in a dependent framework consider a fixed kernel, namely \( h \equiv h_{i_1, \ldots, i_m} \) for all \( i_1, \ldots, i_m \). Our work is the first to consider time dependent kernel functions which makes the theoretical analysis more challenging since the standard splitting method can be unworkable (cf. Section 2.5). In Section 3.4.1 and 3.4.2, we stress the importance of working with index-dependent kernels for practical applications and we show on a specific example that one can reach significantly faster convergence rates with this approach.

For the first time, we provide in this paper a Bernstein-type concentration inequality for U-statistics of order 2 in a dependent framework with kernels that may depend on the indexes of the sum and that are not assumed to be symmetric or smooth. We work on a general state space with bounded kernels that are \( \pi \)-canonical. This latter notion was first introduced in [20] who proved a variance inequality for U-statistics of ergodic Markov chains. Our Bernstein bound holds for stationary chains but we provide a Hoeffding-type inequality without any assumption on the initial distribution of the Markov chain.

1.1. Outline

In Section 2, we present and comment the assumptions under which our main results hold. In Section 3.1, we define and comment the key quantities involved in our results and we present our exponential inequalities with Theorems 1 and 2 in Section 3.2. Section 3.3 is dedicated to discussions where we give examples of Markov chains satisfying our assumptions and where we compare our results with the independent case. The proofs of both Theorems are presented in Section 4. In the Supplement, we provide the proof of some technical lemmas.
2. Assumptions and notations

We consider a Markov chain \((X_i)_{i \geq 1}\) with transition kernel \(P : E \times E \to \mathbb{R}\) taking values in a measurable space \((E, \Sigma)\), and we introduce bounded functions \(h_{i,j} : E^2 \to \mathbb{R}\). In this section, we describe the different assumptions on the Markov chain \((X_i)_{i \geq 1}\) and on the functions \(h_{i,j}\) that we will consider in Theorems 1 and 2 presented in the next section.

2.1. Uniform ergodicity

Assumption 1. The Markov chain \((X_i)_{i \geq 1}\) is \(\psi\)-irreducible for some maximal irreducibility measure \(\psi\) on \(\Sigma\) (see [34, Section 4.2]). Moreover, there exist an integer \(m \geq 1\), \(\delta_m > 0\) and some probability measure \(\mu\) such that
\[
\forall x \in E, \forall A \in \Sigma, \quad \delta_m \mu(A) \leq P^m(x, A).
\]

We denote \(\pi\) the unique invariant distribution of the Markov chain \((X_i)_{i \geq 1}\).

For the reader familiar with the theory of Markov chains, Assumption 1 states that the whole space \(E\) is a small set which is equivalent to the uniform ergodicity of the Markov chain \((X_i)_{i \geq 1}\) (see [34, Theorem 16.0.2]), namely there exist constants \(0 < \rho < 1\) and \(L > 0\) such that
\[
\parallel P^n(x, \cdot) - \pi \parallel_{TV} \leq L \rho^n, \quad \forall n \geq 0, \pi-a.e \, x \in E,
\]
where \(\pi\) is the unique invariant distribution of the chain \((X_i)_{i \geq 1}\) and where for any measure \(\omega\) on \((E, \Sigma)\), \(\parallel \omega \parallel_{TV} := \sup_{A \in \Sigma} |\omega(A)|\) is the total variation norm of \(\omega\). From [19, section 2.3]), we also know that the Markov chain \((X_i)_{i \geq 1}\) admits an absolute spectral gap \(1 - \lambda > 0\) with \(\lambda \in [0, 1)\) (thanks to uniform ergodicity). We refer to [18, Section 3.1] for a reminder on the spectral gap of Markov chains.

2.2. Upper-bounded Markov kernel

Assumption 2 can be read as a reverse Doeblin’s condition and allows us to achieve a change of measure in expectations in our proof to work with i.i.d. random variables with distribution \(\nu\). As a result, Assumption 2 is the cornerstone of our approach since it allows to decouple the U-statistic in the proof.

Assumption 2. There exist \(\delta_M > 0\) and some probability measure \(\nu\) such that
\[
\forall x \in E, \forall A \in \Sigma, \quad P(x, A) \leq \delta_M \nu(A).
\]

Assumption 2 has already been used in the literature (see [32, Section 4.2]) and was introduced in [13]. This condition can typically require the state space to be compact as highlighted in [32].

Let us describe another situation where Assumption 2 holds. Consider that \((E, \| \cdot \|)\) is a normed space and that for all \(x \in E\), \(P(x, dy)\) has density \(p(x, \cdot)\) with respect to some measure \(\eta\) on \((E, \Sigma)\). We further assume that there exists an integrable function \(u : E \to \mathbb{R}_+\) such that \(\forall x, y \in E, \quad p(x, y) \leq u(y)\). Then considering for \(\nu\) the probability measure with density \(u/\|u\|_1\) with respect to \(\eta\) and \(\delta_M = \|u\|_1\), Assumption 2 holds.
2.3. Exponential integrability of the regeneration time

We introduce some additional notations which will be useful to apply Talagrand concentration result from [37]. Note that this section is inspired from [1] and [34, Theorem 17.3.1]. We assume that Assumption 1 is satisfied and we extend the Markov chain \((X_i)_{i \geq 1}\) to a new (so called split) chain \((\tilde{X}_n, R_n) \in E \times \{0, 1\}\) (see [34, Section 5.1] for a reminder on the splitting technique), satisfying the following properties.

- \((\tilde{X}_n)_n\) is again a Markov chain with transition kernel \(P\) with the same initial distribution as \((X_n)_n\). We recall that \(\pi\) is the invariant distribution on the \(E\).
- if we define \(T_1 = \inf\{n > 0 : R_{nm} = 1\}\),

\[
T_{i+1} = \inf\{n > 0 : R_{(T_i + \cdots + T_i + n)m} = 1\},
\]

then \(T_1, T_2, \ldots\) are well defined and independent. Moreover \(T_2, T_3, \ldots\) are i.i.d.
- if we define \(S_i = T_1 + \cdots + T_i\), then the “blocks”

\[
Y_0 = (\tilde{X}_1, \ldots, \tilde{X}_{mT_1+1}), \quad \text{and} \quad Y_i = (\tilde{X}_{m(S_i+1)}, \ldots, \tilde{X}_{m(S_i+1)}-m), \quad i > 0,
\]

form a one-dependent sequence (i.e. for all \(i, \sigma((Y_j)_{j<i})\) and \(\sigma((Y_j)_{j>i})\) are independent). Moreover, the sequence \(Y_1, Y_2, \ldots\) is stationary and if \(m = 1\) the variables \(Y_0, Y_1, \ldots\) are independent. In consequence, for any measurable space \((S, \mathcal{B})\) and measurable functions \(f : S \to \mathbb{R}\), the variables

\[
Z_i = Z_i(f) = \sum_{j=m(S_i+1)}^{m(S_{i+1}+1)-1} f(\tilde{X}_j), \quad i \geq 1,
\]

constitute a one-dependent sequence (an i.i.d. sequence if \(m = 1\)). Additionally, if \(f\) is \(\pi\)-integrable (recall that \(\pi\) is the unique stationary measure for the chain), then

\[
\mathbb{E}[Z_i] = \delta_m^{-1} m \int f \, d\pi.
\]

- the distribution of \(T_1\) depends only on \(\pi, P, \delta_m, \mu\), whereas the law of \(T_2\) only on \(P, \delta_m\) and \(\mu\).

**Remark** Let us highlight that \((\tilde{X}_n)_n\) is a Markov chain with transition kernel \(P\) and same initial distribution as \((X_n)_n\). Hence for our purposes of estimating the tail probabilities, we will identify \((X_n)_n\) and \((\tilde{X}_n)_n\).

To derive a concentration inequality, we use the exponential integrability of the regeneration times which is ensured if the chain is uniformly ergodic as stated by Proposition 1. A proof can be found in Section C.1 of the Supplement.

**Definition 1.** For \(\alpha > 0\), define the function \(\psi_\alpha : \mathbb{R}_+ \to \mathbb{R}_+\) with the formula \(\psi_\alpha(x) = \exp(x\alpha) - 1\). Then for a random variable \(X\), the \(\alpha\)-Orlicz norm is given by

\[
\|X\|_{\psi_\alpha} = \inf\{\gamma > 0 : \mathbb{E}[\psi_\alpha(|X|/\gamma)] \leq 1\}.
\]

**Proposition 1.** If Assumption 1 holds, then

\[
\|T_1\|_{\psi_1} < \infty \quad \text{and} \quad \|T_2\|_{\psi_1} < \infty,
\]

where \(\| \cdot \|_{\psi_1}\) is the 1-Orlicz norm introduced in Definition 1. We denote \(\tau := \max(\|T_1\|_{\psi_1}, \|T_2\|_{\psi_1})\).
2.4. $\pi$-canonical and bounded kernels

With Assumption 3, we introduce the notion of $\pi$-canonical kernel which is the counterpart of the canonical property from [22].

**Assumption 3.** Let us denote $\mathcal{B}(\mathbb{R})$ the Borel algebra on $\mathbb{R}$. For all $i, j \in [n]$, we assume that $h_{i,j} : (E^2, \Sigma \otimes \Sigma) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ is measurable and is $\pi$-canonical, namely

$$\forall x, y \in E, \quad E_{\pi}[h_{i,j}(X, x)] = E_{\pi}[h_{i,j}(X, y)] = E_{\pi}[h_{i,j}(x, X)] = E_{\pi}[h_{i,j}(y, X)].$$

This common expectation will be denoted $E_{\pi}[h_{i,j}]$.

Moreover, we assume that for all $i, j \in [n]$, $\|h_{i,j}\|_{\infty} < \infty$.

**Remarks**

- A large span of kernels are $\pi$-canonical. This is the case of translation-invariant kernels which have been widely studied in the Machine Learning community. Another example of $\pi$-canonical kernel is a rotation invariant kernel when $E = S^{d-1} := \{ x \in \mathbb{R}^d : \|x\|_2 = 1 \}$ with $\pi$ also rotation invariant (see [10] or [15]).

- The notion of $\pi$-canonical kernels is the counterpart of canonical kernels in the i.i.d. framework (see for example [26]). Note that we are not the first to introduce the notion of $\pi$-canonical kernels working with Markov chains. In [20], Fort and al. provide a variance inequality for U-statistics whose underlying sequence of random variables is an ergodic Markov Chain. Their results holds for $\pi$-canonical kernels as stated with [20, Assumption A2].

- Note that if the kernels $h_{i,j}$ are not $\pi$-canonical, the U-statistic decomposes into a linear term and a $\pi$-canonical U-statistic. This is called the Hoeffding decomposition (see [22, p.176]) and takes the following form

$$\sum_{i \neq j} \left( h_{i,j}(X_i, X_j) - E_{(X,Y) \sim \pi \otimes \pi}[h_{i,j}(X, Y)] \right) = \sum_{i \neq j} \tilde{h}_{i,j}(X_i, X_j) - E_{\pi}[\tilde{h}_{i,j}]
+ \sum_{i \neq j} \left( E_{X \sim \pi}[h_{i,j}(X, X_j)] - E_{(X,Y) \sim \pi \otimes \pi}[h_{i,j}(X, Y)] \right)
+ \sum_{i \neq j} \left( E_{X \sim \pi}[h_{i,j}(X_i, X)] - E_{(X,Y) \sim \pi \otimes \pi}[h_{i,j}(X, Y)] \right),$$

where for all $j$, the kernel $\tilde{h}_{i,j}$ is $\pi$-canonical with

$$\forall x, y \in E, \quad \tilde{h}_{i,j}(x, y) = h_{i,j}(x, y) - E_{X \sim \pi}[h_{i,j}(x, X)] - E_{X \sim \pi}[h_{i,j}(X, y)].$$

2.5. Additional technical assumption

In the case where the kernels $h_{i,j}$ depend on both $i$ and $j$, we need Assumption 4. (ii) to prove Theorem 1. Assumption 4. (ii) is a mild condition on the initial distribution of the Markov chain that is used when we apply Bernstein’s inequality for Markov chains from Proposition 4 (see Section C of the Supplement).
Assumption 4. At least one of the following conditions holds.

(i) For all \( i, j \in [n] \), \( h_{i,j} \equiv h_{1,j} \), i.e. the kernel function \( h_{i,j} \) does not depend on \( i \).

(ii) The initial distribution of the Markov chain \( (X_i)_{i \geq 1} \), denoted \( \chi \), is absolutely continuous with respect to the invariant measure \( \pi \) and its density \( \frac{d\chi}{d\pi} \) has finite \( p \)-moment for some \( p \in (1, \infty] \), i.e.

\[
\infty > \left\| \frac{d\chi}{d\pi} \right\|_{\pi,p} := \begin{cases} \left[ \int \left| \frac{d\chi}{d\pi} \right|^p d\pi \right]^{1/p} & \text{if } p < \infty, \\ \text{ess sup} \left| \frac{d\chi}{d\pi} \right| & \text{if } p = \infty. \end{cases}
\]

In the following, we will denote \( q = \frac{p}{p-1} \in [1, \infty) \) (with \( q = 1 \) if \( p = +\infty \)) which satisfies \( \frac{1}{p} + \frac{1}{q} = 1 \).

Assumption 4 is needed at one specific step of our proof where we need to bound with high probability

\[
\sum_{j=2}^{n} E\left[ \left( \sum_{i=1}^{j-1} p_{i,j}(X_i, X'_j) \right)^k \right], \quad \text{with} \quad \forall i, j, \quad \forall x, y \in E, \quad p_{i,j}(x, y) := h_{i,j}(x, y) - E_{\pi}[h_{i,j}],
\]

and where \( (X'_j)_{j \geq 1} \) are i.i.d. random variables with distribution \( \nu \) from Assumption 2. In the case where Assumption 4.(i) holds, we can use for any fixed \( j \in \{2, \ldots, n\} \) the splitting method to decompose the sum \( \sum_{i=1}^{j-1} p_{i,j}(X_i, X'_j) \) in different blocks whose lengths are given by the regeneration times of the split chain. Thanks to Assumption 4.(i), those blocks are independent and we can use standard concentration tools for sums of independent random variables. This approach is valid for any initial distribution of the chain. However, if Assumption 4.(i) is not satisfied, the blocks used to decompose \( \sum_{i=1}^{j-1} p_{i,j}(X_i, X'_j) \) are not independent and the splitting method can no longer be used. To bypass this issue, we need a Bernstein-type concentration inequality for additive functionals of Markov chains with time-dependent functions (see Proposition 4 in Section B.3 of the Supplement). Proposition 4 is a straightforward corollary of [27, Theorem 1] and requires Assumption 4.(ii) to be satisfied. We refer to Section 4.2 and in particular to Section 4.2.1.3 for further details.

3. Main results

3.1. Preliminary comments

Under the assumptions presented in Section 2, Theorem 1 and 2 provided in Section 3.2 give exponential inequalities for the U-statistic

\[
U_{\text{stat}}(n) = \sum_{1 \leq i < j \leq n} \left( h_{i,j}(X_i, X_j) - E[h_{i,j}(X_i, X_j)] \right).
\]

Theorem 1 provides an Hoeffding-type concentration result that holds without any (or mild) condition on the initial distribution of the chain. By assuming that the chain \( (X_i)_{i \geq 1} \) is stationary (meaning that \( X_1 \) is distributed according to \( \pi \)), Theorem 2 gives a Bernstein-type concentration inequality and leads to a better convergence rate compared to Theorem 1.

The proof of our main results relies on a martingale technique conducted by induction at depth \( t_n := \lfloor r \log n \rfloor \) with \( r > 2 (\log(1/\rho))^{-1} \) (see the remark following Assumption 1 for the definition of
The uniform ergodicity of the Markov chain ensured by \( \rho \). With the notations of Section 2, our concentration inequalities involve the following quantities

\[
A := \max_{i,j} \|h_{i,j}\|_{\infty}, \quad C_n^2 := \sum_{j=1}^{n-j} \sum_{i=1}^{j-1} E\left[ E_{X' \sim \nu}[p_{i,j}^2(X_i, X')] \right],
\]

\[
B_n^2 := \max_{0 \leq k \leq t_n} \max_i \sup_x \sum_{j=i+1}^{n} E_{X' \sim \nu}\left(E_{X \sim P^k(y, \cdot)} p_{i,j}(x, X)\right)^2,
\]

\[
C_n^2 := \max_{0 \leq k \leq t_n} \max_i \sup_x \sum_{j=1}^{j-1} E_{X \sim P^k(y, \cdot)} p_{i,j}(\hat{X}, X)^2,
\]

with the convention that \( P^0(y, \cdot) \) is the Dirac measure at point \( y \in E \). Let us comment those terms.

- Understanding of the origin of \( B_n \). \( B_n \) involves suprema over \( k \) ranging from 0 to \( t_n \). The terms in the supremum corresponding to some specific value of \( k \) arise in our proof at the \( k \)-th step of our induction procedure (and will be denoted \( B_k \) in Section 4, so that \( B_n = \sup_{0 \leq k \leq t_n} B_k \)).

- Bounding \( B_n \) with uniform ergodicity. The uniform ergodicity of the Markov chain ensured by Assumption 1 can allow to bound \( B_n \) since for all \( x, y \in E \) and for all \( k \geq 0 \),

\[
\left| E_{X \sim P^k(y, \cdot)} p_{i,j}(x, X) \right| \leq \sup_z |h_{i,j}(x, z)| \times \| P^k(y, \cdot) - \pi \|_{TV}.
\]

- The case where \( \nu = \pi \) and the independent setting

In the specific case where \( \nu = \pi \) (which includes the independent setting), we get that

\[
C_n^2 = \sum_{i,j} E \left\{ \text{Var}_{\hat{X} \sim \pi} \left[ h_{i,j}(X_i, \hat{X}) \right] \right\},
\]

and using Jensen inequality that

\[
B_n^2 \leq \max \left[ \sup_{x,i} \sum_{j=i+1}^{n} \text{Var}_{\hat{X} \sim \pi} \left[ h_{i,j}(x, \hat{X}) \right], \sup_{y,j} \sum_{i=1}^{j-1} \text{Var}_{\hat{X} \sim \pi} \left[ h_{i,j}(\hat{X}, y) \right] \right].
\]

Hence, \( C_n^2 \) and \( B_n^2 \) can be understood as variance terms that would tend to be larger as \( \nu \) moves away from \( \pi \). Let us point out that in the independent setting, all terms for \( k \) ranging from 1 to \( t_n \) in the definition of \( B_n^2 \) vanish but the term corresponding to \( k = 0 \) does not since \( P^0(y, \cdot) \) is the Dirac measure at \( y \). We provide a detailed comparison of our results with known exponential inequalities in the independent setting in Section 3.3.2.

- Bounding \( B_n \) and \( C_n \). A way to read immediately the convergence rates in our main results

Using coarse bounds, one immediately gets that \( B_n \leq A \sqrt{n} \) and \( C_n \leq An \). We prompt the reader to keep in mind these bounds in order to directly see the rate of convergence and the dominant terms in the inequalities from Section 3.2. These bounds can be significantly improved for particular cases as done in the example presented in Section 3.4.2.

### 3.2. Exponential inequalities

We now state our first result Theorem 1 whose proof can be found in Section 4.1.1.
Theorem 1. Let \( n \geq 2 \). We suppose Assumptions 1, 2 and 3 described in Section 2. There exist two constants \( \beta, \kappa > 0 \) such that for any \( u > 0 \),

a) if Assumption 4.(i) is satisfied, it holds with probability at least \( 1 - \beta e^{-u \log(n)} \),

\[
U_{\text{stat}}(n) \leq \kappa \log(n) \left( \left[ A \log(n) \sqrt{n} \right] \sqrt{u} + \left[ A + B_n \sqrt{n} \right] u + \left[ 2A \sqrt{n} \right] u^{3/2} + A \left[ u^2 + n \right] \right).
\]

b) if Assumption 4.(ii) is satisfied, it holds with probability at least \( 1 - \beta e^{-u \log(n)} \),

\[
U_{\text{stat}}(n) \leq \kappa \log(n) \left( \left[ C_n + A \log(n) \sqrt{n} \right] \sqrt{u} + \left[ A + B_n \sqrt{n} \right] u + \left[ 2A \sqrt{n} \right] u^{3/2} + A \left[ u^2 + n \right] \right).
\]

Note that the kernels \( h_{i,j} \) do not need to be symmetric and that we do not consider any assumption on the initial measure of the Markov chain \( (X_i)_{i \geq 1} \) if the kernels \( h_{i,j} \) do not depend on \( i \) (see Assumption 4). By bounding coarsely \( B_n \) and \( C_n \) in Theorem 1 (respectively by \( \sqrt{n} A \) and \( n A \)), we get that there exist constants \( \beta, \kappa > 0 \) such that for any \( u \geq 1 \), it holds with probability at least \( 1 - \beta e^{-u \log n} \),

\[
\frac{2}{n(n-1)} U_{\text{stat}}(n) \leq \kappa \max_{i,j} \| h_{i,j} \|_{\infty} \log n \left\{ \frac{u}{n} + \left[ \frac{u}{n} \right]^2 \right\}.
\]

In particular it holds

\[
\frac{2}{n(n-1)} U_{\text{stat}}(n) = \mathcal{O}_P \left( \frac{\log(n) \log \log n}{n} \right),
\]

where \( \mathcal{O}_P \) denotes stochastic boundedness. Up to a \( \log(n) \log \log n \) multiplicative term, we uncover the optimal rate of Hoeffding’s inequality for canonical U-statistics of order 2, see [28]. Taking a close look at the proof of Theorem 1 (and more specifically at Section 4.3), one can remark that the same results hold if the U-statistic is centered with the expectations \( E_\pi[h_{i,j}] \), namely for

\[
\sum_{1 \leq i < j \leq n} \left( h_{i,j}(X_i, X_j) - E_\pi[h_{i,j}] \right).
\]

It is well-known that one can expect a better convergence rate when variance terms are small with a Bernstein bound. The main limitation in Theorem 1 that prevents us from taking advantage of small variances is the term at the extreme right on the concentration inequality of Theorem 1, namely \( A n \log n \). Working with the additional assumption that the Markov chain \( (X_i)_{i \geq 1} \) is stationary – meaning that the initial distribution of the chain is the invariant distribution \( \pi \) – we are able to prove a Bernstein-type concentration inequality as stated with Theorem 2. The proof of Theorem 2 is provided in Section 4.1.2. Stationarity is only used to bound the remaining terms that were not already considered in the \( t_n \) steps of our induction procedure (see Section 3.1 for the definition of \( t_n \)). We refer to the proof of Proposition 3.b) in Section 4.3 for details.

Theorem 2. We suppose Assumptions 1, 2 and 3 described in Section 2. We further assume that the Markov chain \( (X_i)_{i \geq 1} \) is stationary. Then there exist two constants \( \beta, \kappa > 0 \) such that for any \( u > 0 \), it holds with probability at least \( 1 - \beta e^{-u \log n} \),

\[
U_{\text{stat}}(n) \leq \kappa \log(n) \left( \left[ C_n + A \log(n) \sqrt{n} \right] \sqrt{u} + \left[ A + B_n \sqrt{n} \right] u + \left[ 2A \sqrt{n} \right] u^{3/2} + A \left[ u^2 + \log n \right] \right).
\]

In case where Assumption 4.(i) holds, one can remove \( C_n \) in the previous inequality.
3.3. Discussion

3.3.1. Examples of Markov chains satisfying the Assumptions

In the Section A of the Supplement, we show that Assumptions 1 and 2 are satisfied by any uniformly ergodic Markov chain with finite state space, and for AR(1) or ARCH processes under mild conditions.

3.3.2. The independent setting

In the case where the random variables \((X_i)_{i \geq 1}\) are independent, the terms \(B_n^2\) and \(C_n^2\) involved in our exponential inequality take the following form

\[
B_n^2 = \max \left[ \sup_{i,x} \sum_{j=i+1}^{n} E \left[ p_{i,j}^2(x, X_j) \right], \sup_{j,y} \sum_{i=1}^{j-1} E \left[ p_{i,j}^2(X_i, y) \right] \right],
\]

and

\[
C_n^2 = \sum_{j=2}^{n} \sum_{i=1}^{j-1} E \left[ p_{i,j}(X_i, X_j)^2 \right],
\]

where we remind that all terms for \(k \in \{1, \ldots, t_n\}\) in the definition of \(B_n^2\) in Eq.(3) vanish and it only remains the contribution of terms for \(k = 0\). In the independent setting, [26, Theorem 1] proved that for any \(u > 0\), it holds with probability at least \(1 - 3e^{-u}\),

\[
U_{\text{stat}}(n) \leq C_n \sqrt{u} + (D_n + F_n) u + B_n u^{3/2} + Au^2,
\]

where \(A, B_n\) and \(C_n\) coincide with the terms of this paper (see Eq.(5)). Let us comment the quantities involved in the different regimes of the tail behaviour.

- **Sub-Gaussian.** In Theorem 2, we recover the term \(C_n\) from [26] and we suffer an additional \(A \sqrt{n} \log n\) term.
- **Sub-Exponential.** \(D_n\) and \(F_n\) come from duality arguments in the proof of [26]. We do not recover the counterpart of these terms in Theorem 2 since working with dependent variables bring additional technical difficulties and the use for example of a decoupling argument. \(D_n + F_n\) is replaced by \(A + B_n \sqrt{n}\) in our result.
- **Sub-Weibull with parameter 2/3.** While [26] finds the quantity \(B_n\) for the term \(u^{3/2}\), the counterpart in Theorem 2 is the worst case scenario since it always holds \(B_n \leq A \sqrt{n}\).
- **Sub-Weibull with parameter 1/2.** We obtain the same behaviour for the sub-Weibull (with parameter 1/2) regime of the tail behaviour.

Let us also mention that Theorem 2 has an additive term \(A \log^2 n\) (that will not be dominant for standard choice of \(u\)). This term can be understood as a proof artefact and arises when we bound the remaining terms in the U-statistic that were not considered in our induction procedure. We finally point out that our result involves additive \(\log n\) factors (both in the tail bound and in the probability).

3.4. Connections with the literature

In this section, we describe the concentration inequality obtained in [39] for U-statistics in a dependent framework and we explain the differences with our work. We consider an integer \(n \in \mathbb{N} \setminus \{0\}\) and a geometrically \(\alpha\)-mixing sequence \((X_i)_{i \in \mathbb{N}}\) (see [39, Section 2]) with coefficient

\[
\alpha(i) \leq \gamma_1 \exp(-\gamma_2 i), \quad \text{for all } i \geq 1,
\]
where \( \gamma_1, \gamma_2 \) are two positive absolute constants. We consider a kernel \( h : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R} \) degenerate, symmetric, continuous, integrable and satisfying for some \( q \geq 1 \), \( \int_{\mathbb{R}^{2d}} |\mathcal{F} h(u)||u|^q du < \infty \), where \( \mathcal{F} h \) denotes the Fourier-transform of \( h \). Then Eq.(2.4) from [39] states that there exists a constant \( c > 0 \) such that for any \( u > 0 \), it holds with probability at least \( 1 - 6e^{-u} \)

\[
\frac{2}{n(n-1)} U_{\text{stat}}(n) \leq 4c||\mathcal{F} h||_{L^1} \left\{ A_n^{1/2} \frac{u}{n} + e\log^4(n) \left[ \frac{u}{n} \right]^2 \right\}, \tag{6}
\]

where \( A_n^{1/2} = 4 \left( \frac{64\gamma_1^{1/3}}{1-\exp(-\gamma_2/3)} + \frac{\log^4(n)}{n} \right) \) and \( U_{\text{stat}}(n) = \sum_{1 \leq i < j \leq n} (h(X_i, X_j) - E\pi[h]) \).

[39] has the merit of working with geometrically \( \alpha \)-mixing stationary sequences which includes in particular geometrically (and hence uniformly) ergodic Markov chains (see [29, p.6]). For the sake of simplicity, we presented the result of [39] for \( U \)-statistics of order 2, but their result holds for \( U \)-statistics of arbitrary order \( m \geq 2 \). Nevertheless, they only consider state spaces like \( \mathbb{R}^d \) with \( d \geq 1 \) and they work with a unique kernel \( h \) (i.e. \( h_{i_1,\ldots,i_m} = h \) for any \( i_1, \ldots, i_m \)) which is assumed to be symmetric continuous, integrable and that satisfies some smoothness assumption. On the contrary, we consider general state spaces and we allow different kernels \( h_{i,j} \) that are not assumed to be symmetric or smooth. In addition, Theorem 2 is a Bernstein-type exponential inequality where we can benefit from small variance terms, which is not the case for [39]. We provide a specific example in Section 3.4.2.

### 3.4.1. Motivations for the study of time dependent kernels

In this section, we want to stress the importance of working with weighted \( U \)-statistics for practical applications. In the following, we detail two specific examples borrowed from the fields of information retrieval and of homogeneity tests. Note that one could find other applications such as in genetic association (cf. [45]) or for independence tests (cf. [40]).

#### 3.4.1.1. Average-Precision Correlation

When we search the Internet, the browser computes a numeric score on how well each object in the database matches the query, and rank the objects according to this value. In order to evaluate the quality of this browser, a standard approach in the field of information retrieval consists in comparing the ranking provided by the web search engine and the ranking obtained from human labels (cf. [25]). One way to measure how well both rankings are aligned is to report the correlation between them. One of the most commonly used rank correlation statistic is the Kendall’s \( \tau \). Considering a dataset of size \( n \in \mathbb{N} \) ordered according to the human labels and denoting \( X_i \) the rank the browser gives to the \( i \)-th element, the Kendall’s \( \tau \) is defined by

\[
\tau_{\text{Ken}} := \frac{2}{n(n-1)} \sum_{i \neq j} \left\{ \mathbbm{1}_{X_i > X_j} \mathbbm{1}_{i > j} + \mathbbm{1}_{X_i < X_j} \mathbbm{1}_{i < j} \right\} - 1.
\]

Since only the top ranking objects are shown to the user, it would be legitimate to penalize heavier errors made on items having high rankings. The Kendall’s \( \tau \) does not make such distinctions and new correlation measurements have been popularized to address this issue. One of them is the so-called Average-Precision Correlation (cf. [46]) which is defined by

\[
\tau_{\text{AP}} := \frac{2}{n-1} \sum_{j=2}^{n} \frac{\sum_{i=1}^{j-1} \mathbbm{1}_{X_i < X_j}}{j-1} - 1.
\]

Note that \( \tau_{\text{AP}} \) is a \( U \)-statistic where the kernels \( h_{i,j}(x,y) := \frac{1}{j-1} \) depend on \( j \). Let us point out that \( h_{i,j} \) do not depend on \( i \) so that Assumption 4.(i) holds.
3.4.1.2. Accounting for confounding covariates

U-statistics are powerful tools to compare the distributions of random variables across two groups (say with labels 0 and 1) from samples $X_1, \ldots, X_n$ and $X_{n+1}, \ldots, X_{n+m}$. The typical example is the Wilcoxon Rank Sum Test (WRST) based on the following U-statistic

$$
\sum_{i=1}^{n} \sum_{j=1}^{m} h(X_i, X_{n+j}) \text{ where } h(x, y) := \frac{1}{2} \mathbb{1}_{x < y} + \frac{1}{2} \mathbb{1}_{x \leq y}.
$$

The WRST relies on the following idea: if the data is pooled and then ranked, the average rank of observations from each group should be the same. For any $i \in [n + m]$, let $G_i$ be the random variable valued in $\{0, 1\}$ allocating the $i$-th individual to one of the two groups. Note that the observed allocation $(g_i)_{i \in [n+m]}$ is given by $g_i = 0$ if and only if $i \leq n$. When group membership is not assigned through randomization, there may be confounding covariates $Z$ (assumed to be observed) that can cause a spurious association between outcome and group membership. In that case, we wish rather to test the null hypothesis $P(X \leq t | G = 0, Z = z) = P(X \leq t | Z = z)$. In [38], the authors developed such a test by working with the following adjusted U-statistics involving index-dependent kernels

$$
(\sum_{i : g_i = 0} w(z_i, g_i) \sum_{j : g_j = 1} w(z_j, g_j))^{-1} \sum_{i : g_i = 0} \sum_{j : g_j = 1} h(X_i, X_j) w(z_i, g_i) w(z_j, g_j),
$$

where the weights $w(z_i, g_i) = (P(G = g_i | Z = z_i))^{-1}$ can be estimated with a logistic regression.

3.4.2. Time dependent kernels and convergence rate

In this section, we consider a stationary Markov chain $(X_i)_{i \geq 1}$ satisfying Assumptions 1, 2 and 3. We study the case where there exist reals $(a_{i,j})_{i,j \in \mathbb{N}}$ such that for all $i, j \in \mathbb{N}$, $h_{i,j} = a_{i,j} h$ for some $\pi$-canonical kernel $h : E^2 \to \mathbb{R}$. For simplicity, we consider that $E \pi h = 0$ leading to $p_{i,j} = h_{i,j}$. Let us consider the specific example where $a_{i,j} = |j - i|^{-1}$ for $i \neq j$. In such setting, the coefficients $a_{i,j}$’s are weighting each summand in the U-statistic: the larger $|j - i|$, the smaller is the contribution of the term indexed by $(i, j)$ in the sum. As a result, interpreting indexes as time steps, the $a_{i,j}$’s can be understood as forgetting factors. Since

$$
B_n^2 \leq A^2 \max_i \left\{ \max_{j \neq i+1} n \text{ max}_{j \neq i+1} \frac{1}{j - i - 1} \right\} \leq A^2 \sum_{j=2}^{n} |j - 1|^{-2} \leq A^2,
$$

and

$$
C_n^2 \leq A^2 \sum_{j=2}^{n} \sum_{i=1}^{j-1} \frac{1}{j - i - 1} \leq A^2 \sum_{s=1}^{n} \frac{s^2}{s^2} \leq A^2 \left( 1 + \int_{1}^{n} \frac{1}{x} \, dx \right) \leq A^2 (1 + \log n),
$$

Theorem 2 ensures that there exist constants $\beta, \kappa > 0$ such that for any $u \geq 1$ it holds with probability at least $1 - \beta e^{-u \log n}$,

$$
\frac{2}{n(n-1)} U_{\text{stat}}(n) \leq \kappa A \log n \left( \log(n) \frac{\sqrt{u}}{n^{3/2}} + \left[ \frac{u}{n} \right]^{3/2} + \left[ \frac{u}{n} \right]^2 \right).
$$

In particular, with probability at least $1 - \beta \frac{\log n}{n}$ we have $\frac{2}{n(n-1)} U_{\text{stat}}(n) \leq 3 \kappa A \log^{5/2} n / n^{3/2}$. This convergence rate improves significantly the one obtained from an Hoeffding-type concentration inequality like Eq.(4) that would lead to $U_{\text{stat}}(n) \leq 2 \kappa A \log^{3/2} n$ with probability at least $1 - \beta \frac{\log n}{n}$. 

Concentration inequality for U-statistics of order two for uniformly ergodic Markov chains
4. Proofs

4.1. Proofs of Theorems 1 and 2

Our proof is inspired from [22, Section 3.4.3] where a Bernstein-type inequality is shown for U-statistics of order 2 in the independent setting. Their proof relies on the canonical property of the kernel functions which endowed the U-statistic with a martingale structure. We want to use a similar argument and decompose $\tilde{U}_{\text{stat}}(n)$ to recover the martingale property for each term (except for the last one). Considering for any $l \geq 1$ the σ-algebra $G_l = \sigma(X_1, \ldots, X_l)$, the notation $E_l$ refers to the conditional expectation with respect to $G_l$. Then we decompose $\tilde{U}_{\text{stat}}(n)$ as follows,

$$
\tilde{U}_{\text{stat}}(n) = M(t_n)_{\text{stat}}(n) + R(t_n)_{\text{stat}}(n),
$$

where

$$M(t_n)_{\text{stat}}(n) = \sum_{k=1}^{t_n} \left( \sum_{i<j} \left( E_{j-k}[h_{i,j}(X_i, X_j)] - E_{j-k}[h_{i,j}(X_i, X_j)] \right) \right),$$

$$R(t_n)_{\text{stat}}(n) = \sum_{i<j} \left( E_{j-t_n}[h_{i,j}(X_i, X_j)] - E[h_{i,j}(X_i, X_j)] \right),$$

and where $t_n$ is an integer that scales logarithmically with $n$. We recall that $t_n := \lfloor r \log n \rfloor$ with $r > 2 (\log(1/\rho))^{-1}$ where $\rho \in (0, 1)$ is a constant characterizing the uniform ergodicity of the Markov chain (see Assumption 1). By convention, we assume here that for all $k < 1$, $E_k[\cdot] := E[\cdot]$. Hence the first term that we will consider is given by

$$U_n = \sum_{1 \leq i < j \leq n} h_{i,j}^{(0)}(X_i, X_{j-1}, X_j),$$

where for all $x, y, z \in E$, $h_{i,j}^{(0)}(x, y, z) = h_{i,j}(x, z) - \int_w h_{i,j}(x, w) P(dw)$. We provide a detailed proof of a concentration result for $U_n$ by taking advantage of its martingale structure. Reasoning by induction, we show that the $t_n - 1$ following terms involved in the decomposition (7) of $\tilde{U}_{\text{stat}}(n)$ can be handled using a similar approach. Since the last term $R(t_n)_{\text{stat}}(n)$ of the decomposition (7) has not a martingale property, another argument is required. We deal with $R(t_n)_{\text{stat}}(n)$ exploiting the uniform ergodicity of the Markov chain $(X_i)_{i \geq 1}$ which is guaranteed by Assumption 1 (see [36, Theorem 8]).

The cornerstones of our approach are the following two propositions whose proofs are postponed to Section 4.2 and Section 4.3 respectively.

**Proposition 2.** Let $n \geq 2$. We keep the notations of Sections 2 and 3.1. We suppose Assumptions 1, 2 and 3 described in Section 2. There exist two constants $\beta, \kappa > 0$ such that for any $u > 0$,

a) if Assumption 4.(i) is satisfied, it holds with probability at least $1 - \beta e^{-u \log(n)}$,

$$M(t_n)_{\text{stat}}(n) \leq \kappa \log(n) \left( [A\sqrt{n} \log n] \sqrt{n} + [A + B_n \sqrt{n}] u + [2A\sqrt{n}] u^{3/2} + Au^2 \right).$$

b) if Assumption 4.(ii) is satisfied, it holds with probability at least $1 - \beta e^{-u \log(n)}$,

$$M(t_n)_{\text{stat}}(n) \leq \kappa \log(n) \left( [C_n + A\sqrt{n} \log n] \sqrt{n} + [A + B_n \sqrt{n}] u + [2A\sqrt{n}] u^{3/2} + Au^2 \right).$$
Proposition 3. Let \( n \geq 2 \). We keep the notations of Sections 2 and 3.1. We suppose Assumptions 1, 2 and 3. Then
\[ R_{\text{stat}}^\alpha(n) \leq A(2L + nt_n) . \]
a) \( R_{\text{stat}}^\alpha(n) \leq A(2L + nt_n) . \)
b) if the Markov chain \((X_i)_{i \geq 1}\) is stationary, \( R_{\text{stat}}^\alpha(n) \leq 2LA \left( 1 + t_n + t_n^2 \right) . \)

4.1.1. Proof of Theorem 1
We suppose Assumptions 1, 2, 3 and 4. (respectively 4.(i)) From the decomposition (7) coupled with Proposition 2.a) (respectively Proposition 2.b)) and Proposition 3.a), the result of Theorem 1.a) (respectively Theorem 1.b)) is straightforward.

4.1.2. Proof of Theorem 2
We suppose Assumptions 1, 2 and 3. We assume in addition that the Markov chain is stationary which implies in particular that Assumption 4.(ii) holds. From the decomposition (7) coupled with Proposition 2.b) and Proposition 3.b), the result of Theorem 2 is straightforward. Note that in case Assumption 4.(i) holds, the quantity \( C_n \) (involved in the sub-Gaussian regime of the tail) can be removed from the inequality by simply using Proposition 2.a) rather than Proposition 2.b).

4.2. Proof of Proposition 2
Let us recall that Proposition 2 requires either a mild condition on the initial distribution of the Markov chain or the fact that the kernels \( h_{i,j} \) do not depend on \( i \) (see Assumption 4). One only needs to consider different Bernstein concentration inequalities for sums of functions of Markov chains to go from one result to the other. In this section, we give the proof of Proposition 2 in the case where Assumption 4.(i) holds. We specify the part of the proof that should be changed to get the result when \( h_{i,j} \) may depend on both \( i \) and \( j \) and when Assumption 4.(ii) holds. We make this easily identifiable using the symbol \( \tilde{P} \).

4.2.1. Concentration of the first term of the decomposition of the U-statistic
4.2.1.1. Martingale structure of the U-statistic
Defining \( Y_j = \sum_{i=1}^{j-1} h_{i,j}(X_i, X_{j-1}, X_j), U_n \) can be written as \( U_n = \sum_{j=2}^{n} Y_j \). Since
\[ E_{j-1}[Y_j] = E[Y_j | X_1, \ldots, X_{j-1}] = 0, \]
we know that \((U_k)_{k \geq 2}\) is a martingale relative to the \( \sigma \)-algebras \( G_l, l \geq 2 \). This martingale can be extended to \( n = 0 \) and \( n = 1 \) by taking \( U_0 = U_1 = 0, G_0 = \{ \emptyset, E \}, G_1 = \sigma(X_1) \). We will use the martingale structure of \((U_n)_{n}\) through the following Lemma.

Lemma 1. (cf. [22, Lemma 3.4.6])
Let \((U_m, G_m), m \in \mathbb{N}\), be a martingale with respect to a filtration \( G_m \) such that \( U_0 = U_1 = 0 \). For each \( m \geq 1 \) and \( k \geq 2 \), define the angle brackets \( A_m^k = A_m^k(U) \) of the martingale \( U \) by
\[ A_m^k = \sum_{i=1}^{m} E_{i-1}[(U_i - U_{i-1})^k] \]
(and note \( A_m^1 = 0 \) for all \( k \)). Suppose that for \( \alpha > 0 \) and all \( i \geq 1 \), \( E[|U_i|^\alpha] < \infty \). Then
\[ (\varepsilon_m := e^{\alpha U_m - \sum_{k \geq 2} \alpha^k A_m^k / k!}, G_m), m \in \mathbb{N}, \]
is a supermartingale. In particular, \( E[\varepsilon_m] \leq E[\varepsilon_1] = 1 \), so that, if \( A^k_m \leq w^k_m \) for constants \( w^k_m \geq 0 \); then

\[
E[e^{\alpha U_m}] \leq e^{\sum_{k \geq 2} \alpha^k w^k_m / k!}.
\]

We will also use the following convexity result several times.

**Lemma 2.** [22, page 179] For all \( \theta_1, \theta_2, \varepsilon \geq 0 \), and for all integer \( k \geq 1 \),

\[
(\theta_1 + \theta_2)^k \leq (1 + \varepsilon)^k \theta_1^k + (1 + \varepsilon^{-1})^{k-1} \theta_2^k.
\]

For all \( k \geq 2 \) and \( n \geq 1 \), we have using Assumption 3:

\[
A_n^k = \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} h_{i,j}^{(0)}(X_i, X_{j-1}, X_j) \right]^k \leq V_n^k := \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} h_{i,j}^{(0)}(X_i, X_{j-1}, X_j) \right]^k
\]

\[
= \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} (h_{i,j}(X_i, X_j) - E_{\tilde{X}} h_{i,j}(X_i, \tilde{X}) + E_{\tilde{X}} h_{i,j}(X_i, \tilde{X}) - E_{j-1}[h_{i,j}(X_i, X_j)]) \right]^k
\]

\[
= \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} \left( p_{i,j}(X_i, X_j) + m_{i,j}(X_i, X_{j-1}) \right) \right]^k,
\]

where \( p_{i,j}(x, z) = h_{i,j}(x, z) - E_{\pi} h_{i,j} \) and \( m_{i,j}(x, y) = E_{\pi} h_{i,j} - \int_z h_{i,j}(x, z) P(y, dz) \).

Using Lemma 2 with \( \varepsilon = 1/2 \), we deduce that

\[
V_n^k \leq \sum_{j=2}^{n} E_{j-1} \left( \left[ \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j) \right] + \left[ \sum_{i=1}^{j-1} m_{i,j}(X_i, X_{j-1}) \right] \right)^k \leq \left( \frac{3}{2} \right)^{k-1} \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j) \right]^k + 3^{k-1} \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} m_{i,j}(X_i, X_{j-1}) \right]^k.
\]

Let us remark that

\[
\sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} m_{i,j}(X_i, X_{j-1}) \right]^k = \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} \left( E_{\tilde{X}} h_{i,j}(X_i, \tilde{X}) - E_{j-1}[h_{i,j}(X_i, X_j)] \right) \right]^k
\]

\[
= \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} \left( E_{\tilde{X}} h_{i,j}(X_i, \tilde{X}) - E_{j-1}[h_{i,j}(X_i, X_j)] \right) \right]^k
\]

\[
= \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} \left( E_{\tilde{X}} h_{i,j}(X_i, \tilde{X}) - E_{j-1}[h_{i,j}(X_i, X_j)] \right) \right]^k.
\]
where the last inequality comes from Jensen’s inequality. We obtain the following upper-bound for $V_n^k$,

$$V_n^k \leq 2 \times 3^{k-1} \sum_{j=2}^{n} E_{j-1} \left| \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j) \right|^k \leq 2 \times 3^{k-1} \delta_M \sum_{j=2}^{n} E_{X_j} \left| \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \right|^k,$$

where the random variables $(X_j')$ are i.i.d. with distribution $\nu$ (see Assumption 2). $E_{X_j'}$ denotes the expectation on the random variable $X_j'$.

**Lemma 3.** (cf. [22, Ex.1 Section 3.4]) Let $Z_j$ be independent random variables with respective probability laws $P_j$. Let $k > 1$, and consider functions $f_1, \ldots, f_N$ where for all $j \in [N], f_j \in L^k(P_j)$. Then the duality of $L^p$ spaces and the independence of the variables $Z_j$ imply that

$$\left( \sum_{j=1}^{N} E \left[ |f_j(Z_j)|^k \right] \right)^{1/k} = \sup_{\sum_{j=1}^{N} E[|f_j(Z_j)|^{k/(k-1)}] = 1} \sum_{j=1}^{N} E \left[ f_j(Z_j) \xi_j(Z_j) \right],$$

where the sup runs over $\xi_j \in L^{k/(k-1)}(P_j)$.

Then by the duality result of Lemma 3,

$$\left( V_n^k \right)^{1/k} \leq \left( 2\delta_M \times 3^{k-1} \sum_{j=2}^{n} E_{X_j'} \left| \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \right|^k \right)^{1/k} \leq (2\delta_M)^{1/k} \sup_{\xi \in \mathcal{L}_k} \sum_{j=2}^{n} \sum_{i=1}^{j-1} E_{X_j'} \left[ p_{i,j}(X_i, X_j') \xi_j(X_j') \right].$$

where $\mathcal{L}_k = \left\{ \xi = (\xi_2, \ldots, \xi_n) \text{ s.t. } \forall 2 \leq j \leq n, \xi_j \in L^{k/(k-1)}(\nu) \text{ with } \sum_{j=2}^{n} E[|\xi_j(X_j')|^{k/(k-1)}]^{k-1} = 1 \right\}$.

Let us denote $F$ the subset of the set $\mathcal{F}(E, \mathbb{R})$ of all measurable functions from $(E, \Sigma)$ to $(\mathbb{R}, \mathcal{B}(\mathbb{R}))$ that are bounded by $A$. We set $S := E \times F^{n-1}$. For all $i \in [n]$, we define $W_i$ by

$$W_i := (X_i, 0, \ldots, 0, p_{i,i+1}(X_i, \cdot), p_{i,i+2}(X_i, \cdot), \ldots, p_{i,n}(X_i, \cdot)) \in S.$$

Hence for all $i \in [n], W_i$ is $\sigma(X_i)$-measurable. We define for any $\xi = (\xi_2, \ldots, \xi_n) \in \prod_{i=2}^{n} L^{k/(k-1)}(\nu)$ the function

$$\forall w = (x, p_2, \ldots, p_n) \in S, \quad f_\xi(w) = \sum_{j=2}^{n} \int p_j(y) \xi_j(y) d\nu(y).$$
Then setting $\mathcal{F} = \{ f_\xi : \sum_{j=2}^n E|\xi_j(X'_j)|^{k/(k-1)} = 1 \}$, we have

$$(V_n^k)^{1/k} \leq (2\delta_M)^{1/k} \sup_{f_\xi \in \mathcal{F}} \sum_{i=1}^{n-1} f_\xi(W_i).$$

By the separability of the $L^p$ spaces of finite measures, $\mathcal{F}$ can be replaced by a countable subset $\mathcal{F}_0$. To upper-bound the tail probabilities of $U_n$, we will bound the variable $V_n^k$ on sets of large probability using Talagrand’s inequality. Then we will use Lemma 1 on these sets by means of optional stopping.

**4.2.1.2. Application of Talagrand’s inequality for Markov chains** The proof of Lemma 4 is provided in Section B.1 of the Supplement.

**Lemma 4.** Let us denote

$$Z = \sup_{f_\xi \in \mathcal{F}} \sum_{i=1}^{n-1} f_\xi(W_i), \quad \sigma_k^2 = \mathbb{E} \left[ \sum_{i=1}^{n-1} \sup_{f_\xi \in \mathcal{F}} |f_\xi(W_i)|^2 \right] \quad \text{and} \quad b_k = \sup_{w \in S} \sup_{f_\xi \in \mathcal{F}} |f_\xi(w)|.$$

Then it holds for any $t > 0$,

$$P(Z > \mathbb{E}[Z] + t) \leq \exp \left( -\frac{1}{8\|\Gamma\|^2} \min \left( \frac{t^2}{4\sigma_k}, \frac{t}{b_k} \right) \right),$$

where $\Gamma$ is a $n \times n$ matrix defined in Section B.1 of the Supplement which satisfies $\|\Gamma\| \leq \frac{2L}{1-\rho}$.

Using Lemma 4, we deduce that for any $t > 0$,

$$P \left( (V_n^k)^{1/k} \geq (2\delta_M)^{1/k} \mathbb{E}[Z] + (2\delta_M)^{1/k} \right) \leq \exp \left( -\frac{1}{8\|\Gamma\|^2} \min \left( \frac{t^2}{4\sigma_k}, \frac{t}{b_k} \right) \right),$$

which implies that for any $x \geq 0$,

$$P \left( (V_n^k)^{1/k} \geq (2\delta_M)^{1/k} \mathbb{E}[Z] + (2\delta_M)^{1/k} 2\sigma_k \sqrt{x} + (2\delta_M)^{1/k} b_k x \right) \leq \exp \left( -\frac{x}{8\|\Gamma\|^2} \right).$$

Using the change of variable $x = k8\|\Gamma\|^2 u$ with $u \geq 0$ in the previous inequality leads to

$$P \left( \bigcup_{k=2}^{\infty} (V_n^k)^{1/k} \geq (2\delta_M)^{1/k} \mathbb{E}[Z] + (2\delta_M)^{1/k} \sigma_k 3\|\Gamma\| \sqrt{k} u + (2\delta_M)^{1/k} k8\|\Gamma\|^2 b_k u \right) \leq 1.62e^{-u},$$

because

$$1 \wedge \sum_{k=2}^{\infty} \exp(-ku) \leq 1 \wedge \frac{1}{e^u(e^u - 1)} = \left( e^u \wedge \frac{1}{e^u - 1} \right) e^{-u} \leq \frac{1 + \sqrt{5}}{2} e^{-u} \leq 1.62e^{-u}.$$

Using Lemma 2 twice and using Holder inequality to bound $b_k$ and $\sigma_k^2$, we obtain (9) from Lemma 5. The proof of Lemma 5 is postponed to Section B.2 of the Supplement.
Lemma 5. For any \( u > 0 \), we denote
\[
 w_{n_i}^k := ((1 + \varepsilon)^{k-1} 2\delta_M (E[Z])^k + 2\delta_M (1 + \varepsilon^{-1})^{2k-2} \left( 8 \| \Gamma \|^2 \right)^k (nA^2)A^{k-2}(ku)^k + (1 + \varepsilon)^{k-1} (1 + \varepsilon^{-1})^{k-1} 2\delta_M (3\| \Gamma \|)^k B_0^2 A^{k-2}(ku)^{k/2},
\]
with \( B_0^2 := \max \left[ \max_i \left\| \sum_{j=i+1}^n E_{X \sim \nu} \left[ p_{i,j}(\cdot, X) \right] \right\|_{\infty}, \max_j \left\| \sum_{i=1}^{j-1} E_{X \sim \pi} \left[ p_{i,j}(X, \cdot) \right] \right\|_{\infty} \right] \leq B_n^2,
\]
where the dependence in \( u \) of \( w_{n_i}^k \) is left implicit. Then it holds
\[
P \left( V_n^k \leq w_{n_i}^k \ \forall k \geq 2 \right) > 1 - 1.62e^{-u}.
\]

4.2.1.3. Bounding \( (E[Z])^k \).

The way we bound \( (E[Z])^k \) is the only part of the proof that needs to be modified to get the concentration result when Assumption 4.(i) or Assumption 4.(ii) holds. This is where we can use different Bernstein concentration inequalities according to whether the splitting method is applicable or not (see Section 2.5 for details). Here we present the approach when \( h_{i,j} \equiv h_{1,j} \), \( \forall i, j \) (i.e. when Assumption 4.(i) is satisfied). We refer to Section B.3 of the Supplement for the details regarding the way we bound \( (E[Z])^k \) when Assumption 4.(ii) holds.

Using Jensen inequality and Lemma 3, we obtain
\[
 (E[Z])^k \leq E[Z^k] = E \left[ \left( \sup_{\xi \in \mathcal{L}_k} \left( \sum_{i=1}^{n-1} \sum_{j=i+1}^n E_{X_j} \left[ p_{i,j}(X_i, X_j') \xi_j(X_j') \right] \right)^k \right) \right]
\]
\[
 = E \left[ \sum_{j=2}^n E_{X_j} \left[ \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \right]^k \right] = \sum_{j=2}^n E \left[ \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \right]^k,
\]
where we recall that \( E_{X_j} \) denotes the expectation on the random variable \( X_j' \). One can remark that conditionally to \( X_j' \), the quantity \( \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \) is a sum of function of the Markov chain \( (X_i)_{i \geq 1} \).

Hence to control this term, we apply a Bernstein inequality for Markov chains.

Let us consider some \( j \in [n] \) and some \( x \in E \). Using the notations of Section 2.3, we define
\[
 \forall l \in \{0, \ldots, n\}, \ Z_l^j(x) = \sum_{i=m(S_{l+1})}^{m(S_{l+1})+1-1} p_{i,j}(X_i, x).
\]

By convention, we set \( p_{i,j} \equiv 0 \) for any \( i \geq j \). Let us consider \( N_j = \sup \{ i \in \mathbb{N} : mS_{l+1} + m - 1 \leq j - 1 \} \). Then using twice Lemma 2, we have
\[
 \left| \sum_{i=1}^{j-1} p_{i,j}(X_i, x) \right|^k = \left| \sum_{l=0}^{N_j} Z_l^j(x) + \sum_{i=m(S_{N_j}+1)}^{j-1} p_{i,j}(X_i, x) \right|^k
\]
where for the last inequality we gathered (12) with the left hand side of (11) from Lemma 6. This gives that

\[ X \equiv \langle 12, \text{Lemma 1.2.6} \rangle \]

Lemma 6.

We have \(|\sum_{i=m(S_{N_j+1})}^{j-1} p_{i,j}(X_i,x)| \leq \sum_{i=m(S_{N_j+1})}^{j-1} p_{i,j}(X_i,x)\). First, we use

\[
P \left( \left| \sum_{i=m(S_{N_j+1})}^{j-1} p_{i,j}(X_i,x) \right| \geq t \right) \leq P(T_{N_j+1} \geq \frac{t}{Am}) \leq P(\max(T_1,T_2) \geq \frac{t}{Am})
\]

\[
\leq P(T_1 \geq \frac{t}{Am}) + P(T_2 \geq \frac{t}{Am}) \leq 4 \exp\left(-\frac{t}{Am}\right).
\]

Hence, using that for an exponential random variable \(G\) with parameter 1, \(E[G^p] = p! \; \forall p \geq 0\),

\[
E \left[ \left| \sum_{i=m(S_{N_j+1})}^{j-1} p_{i,j}(X_i,x) \right|^k \right] = 4 \int_0^{\infty} P \left( \left| \sum_{i=m(S_{N_j+1})}^{j-1} p_{i,j}(X_i,x) \right| \geq t \right) dt
\]

\[
\leq 4 \int_0^{\infty} \exp\left(-\frac{t^{1/k}}{Am}\right) \leq 4(Am)^k \int_0^{\infty} \exp(-v)kv^{k-1}dv = 4(Am)^k k!
\]

The random variable \(Z_{2l}^j(x)\) is \(\sigma(X_{m(S_{2l+1})}, \ldots, X_{m(S_{2l+1})-1})\)-measurable. Let us insist that this holds because we consider that \(h_{i,j} \equiv h_{1,j}, \forall i,j\) which implies that \(p_{i,j} \equiv p_{1,j}, \forall i,j\). Hence for any \(x \in E\), the random variables \(Z_{2l}^j(x)\) are independent (see Section 2.3). Moreover, one has that for any \(l\), \(E[Z_{2l}^j(x)] = 0\). This is due to [34, Eq. (17.23) Theorem 17.3.1] together with Assumption 3 which gives that \(\forall x' \in E, \; E_{X \sim \pi}[p_{i,j}(X,x')] = 0\). Let us finally notice that for any \(x \in E\) and any \(l \geq 0\), \(|Z_{2l}^j(x)| \leq AmT_{2l+1}\), so \(\|Z_{2l}^j(x)\|_{\psi_1} \leq Am \max(\|T_1\|_{\psi_1},\|T_2\|_{\psi_1}) \leq Am\tau\). First, we use Lemma 6 to obtain that

\[
E \left[ \left| \sum_{l=0}^{N/2} Z_{2l}^j(x) \right|^k \right] \leq E \max_{0 \leq s \leq n-1} \left| \sum_{l=0}^{s} Z_{2l}^j(x) \right|^k \leq 2 \times 4^k E \left[ \left| \sum_{l=0}^{n-1} Z_{2l}^j(x) \right|^k \right],
\]

where for the last inequality we gathered (12) with the left hand side of (11) from Lemma 6.

Lemma 6. (cf. [12, Lemma 2.1.6])

Let us consider some separable Banach space \(B\) endowed with the norm \(\| \cdot \|\). Let \(X_i, i \leq n,\) be independent centered \(B\)-valued random variables with norms \(L_p\) for some \(p \geq 1\) and let \(\varepsilon_i\) be independent Rademacher random variables independent of the variables \(X_i\). Then

\[
2^{-p} E \left[ \sum_{i=1}^{n} \| \varepsilon_i X_i \|^p \right] \leq E \left[ \sum_{i=1}^{n} \| X_i \|^p \right] \leq 2^p E \left[ \sum_{i=1}^{n} \| \varepsilon_i X_i \|^p \right],
\]
With an analogous approach, we get that
\[ x \]
\[ Y \]
\[ K > \]
\[ \text{(Bernstein's inequality, \cite[Lemma 2.2.11]{43} and the subsequent remark).} \]

Similarly, the random variables \((Z_{2l+1}^j(x))_l\) are independent and satisfy for any \(l\), \(E[Z_{2l+1}^j(x)] = 0\). With an analogous approach, we get that
\[ E \left[ \left| \sum_{l=0}^{[N_j]/2} Z_{2l+1}^j(x) \right|^k \right] \leq E \left[ \max_{0 \leq s \leq n-1} \left| \sum_{l=0}^s Z_{2l+1}^j(x) \right|^k \right] \leq 2 \times 4^k E \left[ \sum_{l=0}^{n-1} Z_{2l+1}^j(x) \right]^k. \]

Let us denote for any \(j \in [n]\), \(E[X_j^t] \) the conditional expectation with respect to the \(\sigma\)-algebra \(\sigma(X_j')\). Coming back to (10), we proved that
\[ E[X_j^t] \left| \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \right|^k \leq \left( \frac{9}{4} \right)^{k-1} E[X_j^t] \left| \sum_{l=0}^{[N_j-1]/2} Z_{2l+1}^j(X_j') \right|^k \]
\[ + \left( \frac{9}{2} \right)^{k-1} E[X_j^t] \left| \sum_{l=0}^{[N_j-1]/2} Z_{2l+1}^j(X_j') \right|^k + 3^{k-1} E[X_j^t] \left| \sum_{i=m(S_{N_j}+1)}^{j-1} p_{i,j}(X_i, X_j') \right|^k \]
\[ \leq 2 \times 9^k E[X_j^t] \left| \sum_{l=0}^{n-1} Z_{2l+1}^j(X_j') \right|^k + 2 \times 18^k E[X_j^t] \left| \sum_{l=0}^{n-1} Z_{2l+1}^j(X_j') \right|^k + 4(3A\tau)^k k!. \]  

It remains to bound the two expectations in (13). The two latter expectations will be controlled similarly and we give the details for the first one. We use the following Bernstein’s inequality with the sequence of random variables \((Z_{2l+1}^j(x))_l\).

**Lemma 7.** (Bernstein’s \(\psi_1\) inequality, \cite[Lemma 2.2.11]{43} and the subsequent remark).

If \(Y_1, \ldots, Y_n\) are independent random variables such that \(EY_i = 0\) and \(\|Y_i\|_{\psi_1} \leq \tau\), then for every \(\tau > 0\),
\[ \mathbb{P}(\sum_{i=1}^{n} Y_i > t) \leq 2 \exp \left( - \frac{1}{K} \min \left( \frac{t^2}{n\tau^2}, \frac{t}{\tau} \right) \right), \]
for some universal constant \(K > 0\) (\(K = 8\) fits).

We obtain
\[ \mathbb{P}(\sum_{l=0}^{n-1} Z_{2l+1}^j(x) > t) \leq 2 \exp \left( - \frac{1}{K} \min \left( \frac{t^2}{nA^2m^2\tau^2}, \frac{t}{A\tau} \right) \right). \]

We deduce that for any \(x \in E\), any \(j \in [n]\) and any \(\tau > 0\),
\[ E \left[ \left| \sum_{l=0}^{n-1} Z_{2l+1}^j(x) \right|^k \right] = \int_0^{\infty} \mathbb{P} \left( \sum_{l=0}^{n-1} Z_{2l+1}^j(x) > t \right) dt \]
$$= 2 \int_0^\infty \exp \left( -\frac{1}{K} \min \left( \frac{t^{2/k}}{nA^2m^2\tau^2}, \frac{t^{1/k}}{Am\tau} \right) \right) dt.$$ 

Let us remark that \( \frac{t^{2/k}}{Am\tau} \leq t \leq (nA\tau m)^k \). Hence for any \( j \in [n] \),

$$E \left[ \sum_{l=0}^{n-1} Z_{2l+1}^j (X_j') \right]^k \leq 2 \int_0^{(nA\tau m)^k} \exp \left( -\frac{t^{2/k}}{K\min(nA^2m^2\tau^2, Am\tau)} \right) dt + 2 \int_{(nA\tau m)^k}^\infty \exp \left( -\frac{t^{1/k}}{KAm\tau} \right) dt.$$ 

\[ \leq 2 \int_0^{n/K} \exp (-v) \frac{k}{2} v^{k/2-1} \left( \sqrt{Kn^{1/2}Am} \right)^k dv + 2 \int_0^\infty \exp (-v) kv^{k-1}(KAm\tau)^k dv. \]

\[ \leq 2 \int_0^{n/K} \exp (-v) \frac{k}{2} v^{k/2-1} \left( \sqrt{Kn^{1/2}Am} \right)^k dv + 2k \times (k-1)(KAm\tau)^k. \]

where we used again that if \( G \) is an exponential random variable with parameter 1, then for any \( p \in \mathbb{N}, E[G^p] = p! \). Since for any real \( l \geq 1 \),

$$\int_0^{n/K} e^{-v} v^{l-1} dv = \sum_{r=0}^{+\infty} \frac{(-1)^r}{r!} \int_0^{n/K} v^{r+l-1} dv = \sum_{r=0}^{+\infty} \frac{(-1)^r (n/K)^{r+l}}{r!(r+l)} \leq \sum_{r=0}^{+\infty} \frac{(-1)^r (n/K)^{r+l}}{r! l} \leq \left( \frac{n}{K} \right)^l e^{-n/K},$$

we get that

$$k \left( \sqrt{Kn^{1/2}Am} \right)^k \int_0^{n/K} e^{-v} v^{k/2-1} dv \leq 2 \left( \sqrt{Kn^{1/2}Am} \right)^k e^{-n/K} (n/K)^{k/2} = 2(nA\tau m)^k e^{-n/K}.$$ 

Hence we proved that for some universal constant \( K > 1 \),

$$E \left[ \sum_{l=0}^{n-1} Z_{2l+1}^j (X_j') \right]^k \leq 2(nA\tau m)^k e^{-n/K} + 2k(KAm\tau)^k \leq 4k(KAm\tau)^k,$$

since for all \( k \geq 2 \), \( e^{-n/K}(n/K)^k/(k!) \leq 1 \). Using a similar approach, one can show the same bound for the second expectation in (13). We proved that for some universal constant \( K > 1 \),

$$\langle E[Z] \rangle^k \leq \sum_{j=2}^{n} \left[ E[X_j'] \left| \sum_{i=1}^{j-1} p_{i,j}(X_i, X_j') \right|^k \right] \leq 2 \times 9^k \sum_{j=2}^{n} \left[ E[X_j'] \left| \sum_{l=0}^{n-1} Z_{2l+1}^j (X_j') \right|^k \right]$$

$$+ 2 \times 18^k \sum_{j=2}^{n} \left[ E[X_j'] \left| \sum_{l=0}^{n-1} Z_{2l+1}^j (X_j') \right|^k \right] + 4 \sum_{j=2}^{n} (3Am\tau)^k k!$$

\[ \leq 2n \times 18^k \times 4k!(KAm\tau)^k + 4n(3Am\tau)^k k! = 16n \times k!(KAm\tau)^k, \tag{14} \]
where in the last inequality, we still call $K$ the universal constant defined by $18K$.

4.2.1.4. Upper-bounding $U_n$ using the martingale structure  

Let

$$T + 1 := \inf\{l \in \mathbb{N} : V_l^k \geq w_n^k \text{ for some } k \geq 2\}.$$ 

Then, the event $\{T \leq l\}$ depends only on $X_1, \ldots, X_l$ for all $l \geq 1$. Hence, $T$ is a stopping time for the filtration $(\mathcal{G}_l)_l$ where $\mathcal{G}_l = \sigma(\{X_i\}_{i \in [l]})$ and we deduce that $U_{l \wedge T}^T := U_{l \wedge T}$ for $l = 0, \ldots, n$ is a martingale with respect to $(\mathcal{G}_l)_l$ with $U_{0}^T = U_0 = 0$ and $U_{1}^T = U_1 = 0$. We remark that $U_j^T - U_{j-1}^T = U_j - U_{j-1}$ if $T \geq j$ and zero otherwise, and that $\{T \geq j\}$ is $\mathcal{G}_{j-1}$ measurable. Then, the angle brackets of this martingale admit the following bound:

$$A_n^k(U^T) = \sum_{j=2}^{n} E_{j-1}[(U_j^T - U_{j-1}^T)^k]$$ 

$$= \sum_{j=2}^{n} E_{j-1}[U_j - U_{j-1}]^k \mathbb{1}_{T \geq j} = \sum_{j=2}^{n} E_{j-1} \left[ \sum_{i=1}^{j-1} h(X_i, X_{j-1}, X_j) \right]^k \mathbb{1}_{T \geq j}$$ 

$$= \sum_{j=2}^{n-1} V_j^k \mathbb{1}_{T=j} + V_n^k \mathbb{1}_{T \geq n} \leq w_n^k \left( \sum_{j=2}^{n-1} \mathbb{1}_{T=j} + \mathbb{1}_{T \geq n} \right) \leq w_n^k,$$

since, by definition of $T$, $V_j^k \leq w_n^k$ for all $k$ on $\{T \geq j\}$. Hence, Lemma 1 applied to the martingale $U_n^T$ implies

$$\mathbb{E}e^{\alpha U_n^T} \leq \exp \left( \sum_{k \geq 2} \frac{\alpha^k}{k!} w_n^k \right).$$

Also, since $V_n^k$ is nondecreasing in $n$ for each $k$, inequality (9) implies that

$$\mathbb{P}(T < n) \leq \mathbb{P} \left( V_n^k \geq w_n^k \text{ for some } k \geq 2 \right) \leq 1.62e^{-u}.$$

Thus we deduce that for all $s \geq 0$,

$$\mathbb{P}(U_n \geq s) \leq \mathbb{P}(U_n^T \geq s, T \geq n) + \mathbb{P}(T < n) \leq e^{-\alpha s} \exp \left( \sum_{k \geq 2} \frac{\alpha^k}{k!} w_n^k \right) + 1.62e^{-u}. \quad (15)$$

The final step of the proof consists in simplifying $\exp \left( \sum_{k \geq 2} \frac{\alpha^k}{k!} w_n^k \right)$.

$$\sum_{k \geq 2} \frac{\alpha^k}{k!} w_n^k = 2\delta_M \sum_{k \geq 2} \frac{\alpha^k}{k!} (1 + \varepsilon)^{k-1}(E[Z])^k$$ 

$$+ 2\delta_M \sum_{k \geq 2} \frac{\alpha^k}{k!} (2 + \varepsilon + \varepsilon^{-1})^{k-1} (3\|\Gamma\|)^k \mathbb{E}[A]^{k-2}(nk\varepsilon)^{k/2}$$
Using the bound Eq. (14) obtained on \((EZ)^k\), Lemma 8 bounds the three sums \(a_1, a_2\) and \(a_3\).

**Lemma 8.** \(\exp\left(\sum_{k \geq 2} \frac{\alpha_k}{k!} W_k n_k^k\right) \leq \exp\left(\frac{a^2 W^2}{1 - c}\right)\) where

\[
W = 6\sqrt{\delta_M}(1 + \varepsilon)^{1/2} n^{1/2} KA\tau_m
+ \sqrt{2\delta_M(2 + \varepsilon + \varepsilon^{-1})^{1/2} \Gamma \|2\|\sqrt{nu} + \sqrt{2\delta_M A(1 + \varepsilon^{-1})8\|\Gamma\|^2\sqrt{nu}},
\]

and \(c = \max\left[(1 + \varepsilon)KA\tau_m, (2 + \varepsilon + \varepsilon^{-1})A(nu)^{1/2}, (1 + \varepsilon^{-1})^2(8\|\Gamma\|^2)A\sqrt{nu}\right].\)

The proof of Lemma 8 can be found in Section B.4 of the Supplement. Using the result from Lemma 8 in (15) and taking \(s = 2W\sqrt{u} + cu\) and \(\alpha = \sqrt{u}/(W + c\sqrt{u})\) in this inequality yields

\[
P(U_n \geq 2W\sqrt{u} + cu) \leq e^{-u} + 1.62e^{-u} \leq (1 + e)e^{-u}.
\]

By taking \(\varepsilon = 1/2\), we deduce that for any \(u \geq 0\), it holds with probability at least \(1 - (1 + e)e^{-u}\)

\[
\sum_{i < j} h_j^{(0)}(X_i, X_{j-1}, X_j) \leq 12\sqrt{\delta_M KA\tau_m}\sqrt{nu} + 18\sqrt{\delta_M \|\Gamma\|2\|\sqrt{nu}}
+ 100\sqrt{\delta_M \|\Gamma\|^2A\sqrt{nu}3^2/2 + 3K\tau_mu + 27A\|\Gamma\|^2\sqrt{nu}u3/2 + 72A\|\Gamma\|^2cu^2/2,
\]

Denoting \(\kappa := \max(12\sqrt{\delta_M KA\tau_m}, 18\sqrt{\delta_M \|\Gamma\|}, 100\sqrt{\delta_M \|\Gamma\|^2e}, 3K\tau_m, 72\|\Gamma\|^2e)\), we have with probability at least \(1 - (1 + e)e^{-u}\)

\[
\sum_{i < j} h_j^{(0)}(X_i, X_{j-1}, X_j) \leq \kappa \left(A\sqrt{nu} + (A + 2\|\sqrt{n}\})u + 2A\sqrt{nu}3/2 + Au^2\right).
\]

**4.2.2. Reasoning by descending induction with a logarithmic depth**

As previously explained, we apply a proof similar to the one of the previous subsection on the \(t_n := \lfloor r \log n \rfloor\) terms in the sum \(M_{stat}(t_n)\) (see (7)), with \(r > 2(\log(1/\rho))^{-1}\). Let us give the key elements to justify such approach by considering the second term of the sum \(M_{stat}(t_n)\), namely

\[
\sum_{i < j} \left(E_{j-1}\left[h_{i,j}(X_i, X_j)\right]\right) - E_{j-2}\left[h_{i,j}(X_i, X_j)\right]
= \sum_{i = 1}^{n-2} \sum_{j = i+2}^{n} h_{i,j}^{(1)}(X_i, X_{j-2}, X_{j-1}) + \sum_{i = 1}^{n-1} \left\{E_i\left[h_{i,i+1}(X_i, X_{i+1})\right] - E_{i-1}\left[h_{i,i+1}(X_i, X_{i+1})\right]\right\}
= T_{n-1}^{(1)} + \ldots + T_{1}^{(1)} =: T_n^{(1)}.
\]

where \(h_{i,j}^{(1)}(x, y, z) = \int_y h_{i,j}(x, w) P(z, dw) - \int_y h_{i,j}(x, w) P^2(y, dw)\). Using McDiarmid’s inequality for Markov chain (see [35, Corollary 2.10 and Remark 2.11]), we obtain Lemma 9.
Lemma 9. Let us consider \( l \in \{1, \ldots, t_n\} \). For any \( u > 0 \), it holds with probability at least \( 1 - 2e^{-u} \),

\[
\sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \left( E_{j-l} \left[ h_{i,j}(X_i, X_j) \right] - E_{j-l-1} \left[ h_{i,j}(X_i, X_j) \right] \right) \leq 3At_n \sqrt{t_{mix}} nu,
\]

where \( t_{mix} \) is the mixing time of the Markov chain and is given by

\[
t_{mix} := \min \left\{ t \geq 0 : \sup_x \| P^t(x, \cdot) - \pi \|_{TV} < \frac{1}{4} \right\}.
\]

Lemma 9 allows to bound \((*)\) in (17) (by choosing \( l = 1 \)). Now we aim at proving a concentration result for the term

\[
U_{n-1}^{(1)} = \sum_{j=2}^{n-1} \sum_{i=1}^{j-1} h_{i,j}^{(1)}(X_i, X_{j-1}, X_j),
\]

using an approach similar to the one of the previous subsection. A detailed proof can be found in the Section B.5 of the Supplement and we simply state here the concentration result for \( U_{n-1}^{(1)} \) with Lemma 10.

Lemma 10. For any \( u > 0 \), it holds with probability at least \( 1 - (1 + e) e^{-u} \),

\[
U_{n-1}^{(1)} = \sum_{i=1}^{n-2} \sum_{j=i+1}^{n-1} h_{i,j}^{(1)}(X_i, X_{j-1}, X_j) \leq \kappa \left( A \sqrt{n} \sqrt{u} + (A + B_n \sqrt{n})u + 2A \sqrt{n} u^{3/2} + Au^2 \right)
\]

Going back to (17) and using both Lemmas 9 and 10, we get that for any \( u > 0 \), it holds with probability at least \( 1 - (1 + e + 2)e^{-u} \),

\[
\sum_{i < j} \left( E_{j-1} \left[ h_{i,j}(X_i, X_j) \right] - E_{j-2} \left[ h_{i,j}(X_i, X_j) \right] \right) \leq \kappa \left( A \sqrt{n} \sqrt{u} + (A + B_n \sqrt{n})u + 2A \sqrt{n} u^{3/2} + Au^2 \right) + 3At_n \sqrt{t_{mix}} nu
\]

One can do the same analysis for the \( t_n \) first terms in the decomposition (7). Still denoting \( \kappa \) the constant \( \kappa + 3\sqrt{t_{mix}} \), we get that for any \( u > 0 \) it holds with probability at least \( 1 - (3 + e)e^{-u}t_n \),

\[
M^{(t_n)}_{stat}(n) \leq \kappa t_n \left( A t_n \sqrt{n} \sqrt{u} + (A + B_n \sqrt{n})u + 2A \sqrt{n} u^{3/2} + Au^2 \right).
\]

4.3. Proof of Proposition 3

In the following, we assume that \( t_n \leq n \), otherwise \( R_{stat}^{(t_n)}(n) \) is an empty sum. Using our convention which states that for all \( k < 1 \), \( E_k[.] := E[.] \), we need to control

\[
\left| R_{stat}^{(t_n)}(n) \right| = \left| \sum_{i < j} \left( E_{j-t_n} \left[ h_{i,j}(X_i, X_j) \right] - E \left[ h_{i,j}(X_i, X_j) \right] \right) \right| \leq (1) + (2),
\]

where \( t_n \) is the mixing time of the Markov chain and is given by

\[
t_n := \min \left\{ t \geq 0 : \sup_x \| P^t(x, \cdot) - \pi \|_{TV} < \frac{1}{4} \right\}.
\]
with denoting $H_{i,j} = E_{j-t_n} [h_{i,j}(X_i, X_j)] - E [h_{i,j}(X_i, X_j)]$

\[
(1) := \left| \sum_{t_n+1}^{n} \sum_{j=i}^{n} H_{i,j} \right| = \left| \sum_{j=t_n+1}^{n} \sum_{i=1}^{n} H_{i,j} \right|
\]

and

\[
(2) := \left| \sum_{i=1}^{n-1} \sum_{j=i}^{n} H_{i,j} \right| = \left| \sum_{j=2}^{n} \sum_{i=\max(j-t_n+1,1)}^{j-1} H_{i,j} \right|.
\]

We start by bounding the term (1) regardless of the initial distribution of the chain. We will bound in different ways the term (2) depending on whether the Markov chain is stationary or not. Let us first bound the term (1) splitting it in two terms,

\[
(1) = \left| \sum_{j=t_n+1}^{n} \sum_{i=1}^{n} E_{j-t_n} [h_{i,j}(X_i, X_j)] - E [h_{i,j}(X_i, X_j)] \right| \leq (1a) + (1b).
\]

Using Assumption 3, it holds $E_{\pi} [h_{i,j}] = E_{X \sim \pi} [h_{i,j}(X_i, X)] = \int x h_{i,j}(x_i, x) d\pi(x)$. Hence we get that

\[
(1a) := \left| \sum_{j=t_n+1}^{n} \sum_{i=1}^{n} E_{j-t_n} [h_{i,j}(X_i, X_j)] - E_{\pi} [h_{i,j}] \right|
\]

\[
\leq \sum_{j=t_n+1}^{n} \left| \int x \sum_{i=1}^{j-t_n} h_{i,j}(X_i, x_j) \left( P^{t_n}(X_{j-t_n}, x_j) - d\pi(x_j) \right) \right|
\]

\[
\leq \sum_{j=t_n+1}^{n} \left( \sum_{i=1}^{j-t_n} h_{i,j}(X_i, x_j) \right) \sup_{x_j} \left\| P^{t_n}(x, \cdot) - \pi \right\|_{TV}
\]

\[
\leq \sum_{j=t_n+1}^{n} \left( \sum_{i=1}^{j-t_n} h_{i,j}(X_i, x_j) \right) \frac{L \rho^{t_n}}{n^2} \leq \sum_{j=t_n+1}^{n} \left( \sum_{i=1}^{j-t_n} h_{i,j}(X_i, x_j) \right) \frac{L}{n^2} \leq LA,
\]

where in the penultimate inequality we used that $\rho^{t_n} \leq \rho^{n \log(n)} = n^{r \log(\rho)} \leq n^{-2}$. Indeed $2 + r \log(\rho) < 0$ because we choose $r$ such that $r > 2/(\log(1/\rho))^{-1}$.

Using again Assumption 3, it holds $E_{\pi} [h_{i,j}] = \int x \chi P^{j-i}(dx_i) \int x h_{i,j}(x_i, x) d\pi(x)$ where $\chi$ is the initial distribution of the Markov chain $(X_i)_{i \geq 1}$. We get that

\[
(1b) := \left| \sum_{j=t_n+1}^{n} \sum_{i=1}^{n} E_{\pi} [h_{i,j}] - E [h_{i,j}(X_i, X_j)] \right|
\]

\[
\leq \sum_{j=t_n+1}^{n} \sum_{i=1}^{j-t_n} \int x \int x h_{i,j}(x_i, x_j) \chi P^{j-i}(dx_i) \left( P^{j-i}(x_i, x_j) - d\pi(x_j) \right)
\]
Without assuming that the Markov chain is stationary, we bound coarsely (2) as follows

\[
\leq \sum_{j=t_n+1}^{n} \sum_{i=1}^{j-t_n} \|h_{i,j}\|_\infty \int_{x_i} \chi_{P^i}(dx_i) \sup_{z} \int_{x_j} P^{j-i}(z, dx_j) - d\pi(x_j)
\]

\[
\leq \sum_{j=t_n+1}^{n} \sum_{i=1}^{j-t_n} \|h_{i,j}\|_\infty \rho^{j-i} \leq \sum_{j=t_n+1}^{n} \sum_{i=1}^{j-t_n} \|h_{i,j}\|_\infty \rho^{j-i} \leq LA,
\]

where in the penultimate inequality we used that \(\rho^{t_n} \leq \rho^{r \log(n)} = n^{r \log(\rho)} \leq n^{-2}\).

### 4.3.1. Bounding (2) without stationarity

Without assuming that the Markov chain is stationary, we bound coarsely (2) as follows

\[
(2) = \left| \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-1} E_{j-t_n} [h_{i,j}(X_i, X_j)] - E [h_{i,j}(X_i, X_j)] \right| \leq An_t.
\]

This concludes the proof of Proposition 3.3 since we obtain, \(R_{\text{stat}}^i(t_n) \leq A(2L + nt_n)\).

### 4.3.2. Bounding (2) with stationarity

Considering now that the chain is stationary, we split (2) in three different contributions.

\[
(2) = \left| \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-1} E_{j-t_n} [h_{i,j}(X_i, X_j)] - E [h_{i,j}(X_i, X_j)] \right| \leq (2a) + (2b) + (2c),
\]

with

\[
(2a) := \left| \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-[\frac{nt_n}{j}]} E_{j-t_n} [h_{i,j}(X_i, X_j)] - E [h_{i,j}] \right|,
\]

\[
(2b) := \left| \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-[\frac{nt_n}{j}]} E [h_{i,j}] - E [h_{i,j}(X_i, X_j)] \right|,
\]

and

\[
(2c) := \left| \sum_{j=2}^{n} \sum_{i=(j-[\frac{nt_n}{j}]+1)\lor 1}^{j-1} E_{j-t_n} [h_{i,j}(X_i, X_j)] - E [h_{i,j}(X_i, X_j)] \right|.
\]

The only place where we use the stationarity of the chain is to bound the terms (2b) and (2c) by writing that \(E[h_{i,j}(X_i, X_j)] = \int_{x_i} \int_{x_j} d\pi(x_i) P^{j-i}(x_i, dx_j)\). Both are bounded using similar ideas, that’s why we show here how to deal with (2b) and we postpone the proof of Lemma 11 to Section B.6 of the Supplement.

**Lemma 11.** It holds \((2a) \leq LA t_n\) and \((2c) \leq 2LA t_n^2\).

\[
(2b) := \left| \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-[\frac{nt_n}{j}]} E [h_{i,j}] - E [h_{i,j}(X_i, X_j)] \right|.
\]
\[ \leq \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-\lceil \frac{t_n}{2} \rceil} \left| \int_{x_i}^{x_j} \int_{x_j}^{x_i} h_{i,j}(x_i, x_j) d\pi(x_i) \left( d\pi(x_j) - P^{j-i}(x_i, dx_j) \right) \right| \]

\[ \leq \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-\lceil \frac{t_n}{2} \rceil} \|h_{i,j}\|_{\infty} \sup_{y} \left| \int_{x_i}^{x_j} d\pi(x_i) \frac{1}{\sup_{y} \|P^{j-i}(y, \cdot) - \pi\|_{\text{TV}}} \int_{x_j}^{x_i} d\pi(x_j) - P^{j-i}(y, dx_j) \right| \]

\[ \leq \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-\lceil \frac{t_n}{2} \rceil} \|h_{i,j}\|_{\infty} L^{j-i} \leq \sum_{j=2}^{n} \sum_{i=(j-t_n+1)\lor 1}^{j-\lceil \frac{t_n}{2} \rceil} \|h_{i,j}\|_{\infty} L^{j-n/2} \leq LA_{\text{stat}}, \]

where we used that \( \rho^{j-n/2} \leq \rho^{r \log(n)/2} = n^{r \log(\rho)/2} \leq n^{-1}. \) Indeed \( 1 + r \log(\rho)/2 < 0 \) because we choose \( r \) such that \( r > 2(\log(1/\rho))^{-1}. \) Coming back to Eq. (19), we deduce that \( R_{\text{stat}}^{(t_n)}(n) \leq AL \left( 2 + 2t_n + 2t_n^2 \right) \) which concludes the proof of Proposition 3.

This work was supported by a grant from Région Ile de France. The authors gratefully acknowledge the constructive comments and recommendations of the editor and of the anonymous reviewers which definitely help to improve the readability and quality of the paper.

Supplementary Material

Section A: Examples of Markov chains satisfying our Assumptions
We detail the three examples of Markov chains satisfying Assumptions 1 and 2 given in Section 3.3.1.

Section B: Proofs of technical Lemmas
We prove Lemmas useful to prove Proposition 2 and Proposition 3.

Section C: Additional proofs
This section contains mainly of proof of an Hoeffding-type concentration inequality for Markov chains that holds without condition on the initial distribution of the chain.
